KEY TERMS AND DEFINITIONS

Culture: The interactive aggregate of common characteristics that influence a human group's response to its environment, determines the identity of a human group in the same way as personality determines the identity of an individual.

Indigenous: Traditions; social, cultural, economic and political characteristics that are distinct to a particular group of people or society. Indigenous beliefs, systems and knowledge of practices for the sustainable management of resources.

Values: Important and lasting beliefs or ideals shared by the members of a culture about what is good or bad and desirable or undesirable. They are what the civilized and rational minds cherish, esteem, prize preciously and have inclined attitude for. They are principles or standards of a person or society for the good or benefit of the person or the society concerned.

Integrating Knowledge Management and Business Processes

John Steven Edwards

Aston University, UK

INTRODUCTION

Knowledge has been a subject of interest and enquiry for thousands of years, since at least the time of the ancient Greeks, and no doubt even before that. “What is knowledge” continues to be an important topic of discussion in philosophy.

More recently, interest in *managing* knowledge has grown in step with the perception that increasingly we live in a knowledge-based economy. Drucker (1969) is usually credited with being the first to popularize the knowledge-based economy concept by linking the importance of knowledge with rapid technological change. Karl Wiig coined the term knowledge management (hereafter KM) for a NATO seminar in 1986, and its popularity took off following the publication of Nonaka and Takeuchi’s book *“The Knowledge Creating Company”* (Nonaka & Takeuchi, 1995). Knowledge creation is in fact just one of many activities involved in KM. Others include identifying, acquiring, sharing, retaining, refining, and using knowledge. Heisig (2009) compared 160 different KM frameworks: no fewer than 117 of them included a list of activities. Global interest in KM, both academic and practical, has continued to increase throughout the last two decades, but as these numbers indicate, consensus on the theory underpinning KM remains some way off.

In this article, first the different types of knowledge are outlined, then comes a discussion of various routes by which knowledge management has been implemented. A business process-based route, which enables people, processes and tech-

nology to fit together, is growing in popularity as the best way to deliver effective KM that is integrated into what the organization does. Some examples of the business processes route in use are then given. Finally there is a look towards the future.

BACKGROUND

Types of Knowledge: Tacit and Explicit

Nonaka and Takeuchi’s book (1995) popularized the concepts of tacit and explicit knowledge, as well as KM more generally. They based their thinking on that of Michael Polanyi (1966), expressed most memorably in his phrase “we know more than we can tell”.

It is important to realize that tacit and explicit knowledge are not mutually exclusive concepts. Rather, any piece of knowledge has both tacit and explicit elements, as shown in Figure 1. The size of the inner circle represents the proportion of tacit knowledge: the tacit core at the heart of the knowledge that we “cannot tell”. Figure 1(a) shows a case where the knowledge is almost entirely tacit, as in riding a bicycle. Figure 1(b) shows mainly explicit knowledge, where the tacit core is very small, for example how to process a claim for travel expenses in an organization. Figure 1(c) shows an intermediate case, such as making a piece of furniture, where substantial amounts of both tacit and explicit knowledge are involved.

Figure 1. The relationship between tacit and explicit knowledge

KM Strategies

Hansen, Nohria and Tierney (1999) identified that there are two fundamental KM strategies, codification and personalization. Codification concentrates more on explicit knowledge (typically relying very heavily on information technology), personalization more on tacit knowledge (stressing interactions between people). They advocate that an emphasis on one fundamental KM strategy but also including an element of the other, in an 80-20 proportion, is likely to be the most successful.

ROUTES TO IMPLEMENTING KM

Managers have to translate the goals of any strategic initiative into practical, implementable reality. Even with a clear KM strategy, many organizations find it difficult to implement knowledge management systems successfully, especially to integrate KM into the organization properly. Identifying *who* should be involved in knowledge management, *what* knowledge is being managed, and *why* is it being managed can each be problematic. The routes organizations have attempted to follow can be put into five generic categories.

Knowledge World Route

The practical focus in Nonaka and Takeuchi (1995) was very much on knowledge creation. As a result, organizations attempting to follow

their principles for other aspects of KM, such as sharing or retaining knowledge, found it difficult to integrate abstract ideas about knowledge into what the organization actually does, or could do, or should do. Often only the “why” was considered, not the “who” or even the “what”.

Functional Route

This organizes the implementation around the existing organizational structure. The most commonly found structural elements intended to facilitate learning and knowledge sharing in organizations are departmental groupings based on functions. These have clear advantages for integration in terms of what might be called professional development and allegiance. Davenport and Prusak (1998) report examples of successful knowledge transfer between groups of surgeons, and groups of tunneling engineers, amongst others. However, this functional route also has the disadvantage that it encourages the compartmentalization of knowledge, so that integration may be only within that function, not the whole organization. Indeed, professional divisions can actively prevent sharing of knowledge. It has, for example, taken decades for hospital doctors in the UK National Health Service to allow other professionals such as pharmacists and physiotherapists to participate in decision-making about treatment of individual patients on an equal footing. More broadly, modern Western medical science has come to separate “diet” and “medication”, at least until the very

recent past, in a way that Chinese medicine, for example, never has done. The “functional silos” mentality that tends to result from running an organization in this manner was recognized by authors such as Hammer (1990) when KM was in its infancy. However, they are still commonly encountered, as pointed out by Edwards (2011).

This route is only effective when KM can be bounded within a single function. Where the need for KM to be integrated within the organization is broader, for example transferring knowledge between functions, this route will be counter-productive.

IT-Driven Route

This route assumes that the KM strategy is entirely one of codification, usually into some form of repository. In all but the smallest of organizations, such a codification task evidently requires considerable IT support, and the thrust of this route is that once the “correct” form of IT support for managing knowledge has been chosen, it is simply a matter of a great deal of hard work.

Since it ignores the personalization element of the KM strategy, this route only works in a very limited range of situations where the “what” questions are paramount, and as in Figure 1(b) little tacit knowledge is involved, for example where the main KM task is managing the knowledge held by a company in the form of patents. In other circumstances it may not achieve any improvement in KM at all. One example of this from the author’s experience is of a heavy manufacturing firm. Knowledge management in this organization was seen solely as an information systems issue; the KM group was part of the information systems department. The “solution” was seen in terms of the implementation of a knowledge sharing system based on Lotus Notes™. However, there was no real consideration as to who would share what knowledge with whom or for what specific purpose (“why”). Consequently, the eventual use of the installed IT was poor; the only really successful use was by the knowledge management

project team itself, where the “who” and “why” questions had been properly addressed, not just the “what” questions.

People-Centric Route

By contrast, this route assumes that the KM strategy is entirely one of personalization. By definition, this will answer all the “who” questions that might be involved in KM. Thus in organizations where there is general consensus on “what” knowledge is important and “why” it needs to be managed, such a route may prove effective.

However, this is only likely to be the case in small firms. Larger organizations have become increasingly diverse in their activities, and in the range of specialized knowledge that they need to access. This means that consensus even on what knowledge the organization has, never mind what is important, may be difficult to achieve. On the one hand, it may not be easy for a particular specialist to fully appreciate “what the organization does”. Equally, even the most conscientious senior manager will find it literally impossible to understand all the expertise and knowledge possessed by the specialists in his or her organization. To repeat the much-used quotation from Hewlett Packard CEO Lew Platt (Davenport & Prusak, 1998, p. xii) “If HP knew what HP knows, we would be three times as profitable.”

Business Processes Route

The basic weakness of both the IT-driven and people-centric routes is that they do not explicitly connect with “what the organization does”, thus leaving a potential implementation gap between KM and the business itself. Various management thinkers have presented models of “what the organization does”, for example:

- Porter’s value chain (Porter, 1985),
- Earl’s view of core processes (Earl, 1994), the ones that are done directly for external customers,

- Beer's "System Ones" (Beer, 1985), the systems that make the organization what it is,
- Core competences/competencies as espoused by Hamel and Prahalad (1994).

One of the eight principles of the ISO9000 family of standards for Quality Management Systems is the use of a process approach (ISO, 2012). The ISO9000 term product (or service) realization process is equivalent to Earl's core process or Porter's primary activity.

Although there are some significant differences between these models, their common theme is that the effectiveness – indeed the competitive advantage – of organizations depends not on how they are structured, or on what IT or people resources they have, but on what they do. In the terminology of this article, this means their underlying business processes. Note that business processes exist equally in not-for-profit organizations and the author has always found them happy to use the term.

Business processes possess five characteristics that justify their use as a foundation for implementing knowledge management in organizations.

1. Business processes have identifiable customers, whether internal or external. Knowledge is of little relevance to the organization unless put to use for a customer of some kind.
2. Business processes cut across organizational boundaries. Knowledge flows do not need to, and should not, obey the artificial boundaries within an organization.
3. Business processes consist of a structured set of activities. Choosing the appropriate way to structure activities is an important part of the relevant knowledge.
4. Business processes need to be measured. Without some form of measurement as a comparison, knowledge cannot be validated.
5. While the parts of a business process are important, the overriding requirement is that the overall process works. Valid knowledge in an organizational context must take a holistic view.

An additional argument (Braganza, 2001), is that viewing knowledge management in terms of an organization's processes gives a much-needed *demand-side* view of knowledge. This is complementary to the supply-side view of knowledge that stems, for example, from considerations of 'data leading to information leading to knowledge'. Beer and Earl particularly concentrate on this demand-side perspective. Beer indeed goes even further, to include the informal processes and activities of the organization as well as the more formalized ones. A demand-driven view clearly offers better potential for integration of KM with the rest of "what the organization does".

Thus we see that the knowledge that an organization requires must be related not just to what that organization does, but also to how it does it. Therefore people in organizations should benefit from thinking about this knowledge, and how to manage it, by reference to that organization's business processes.

PEOPLE, PROCESSES, AND TECHNOLOGY

As we have seen, effective KM requires the consideration of both tacit and explicit knowledge. The need is to coordinate people, processes and technology successfully using some kind of KM system. It is important to realize that there is more to a KM system than just technology, and that any deliberate, conscious attempt to manage knowledge in an organization amounts to a KM system. The interaction of the three elements people, processes and technology is shown in Figure 2.

Not only does a knowledge management system consist of more than technology, it is important to realize that the technology used to support KM does not have to be "KM software". Several studies continue to find that generic software such as e-mail, blogs or an Intranet is at least as important as specific software (Edwards, Shaw, & Collier, 2005; Zhou & Fink, 2003).

Figure 2. People, processes, and technology in a KM system

THE DEVELOPMENT OF THE BUSINESS PROCESSES ROUTE TO KM

The business processes route to KM is becoming more widely adopted. In the earlier days of KM it was seen as a “niche” approach, leading to the development of what was termed Business Process Oriented Knowledge Management (BPO-KM) (Heisig, 2001). However, BPO-KM has now become “mainstream”, as shown by examples such as Apostolou, Abecker, and Mentzas (2007), who take a process view of the activities of a management consulting firm, to develop KM support for the delivery of its services; and Mas-Machuca and Costa (2012) who study critical success factors for KM, also in the consulting sector.

Examples of the business processes route may now also be found in many other sectors and countries. The Singapore Ministry of Manpower (Fung, 2006) has used business strategies and processes to drive its blended KM approach rather than “plunging straight into analyzing the KM elements” (Fung, 2006, p. 31). Fung concluded that this dramatically increased the business relevance of the KM initiatives. Several organizations in the construction industry have used an approach based on incorporating KM

within a process improvement model (Jeong, Kagioglou, Haigh, Amaratunga, & Siriwardena, 2006). Geisel (2005) gives examples of how the insurance industry in the USA and in Europe has been building knowledge into its business processes. Dayan and Evans (2006) consider KM as a way to support the process-focussed Capability Maturity Model, and explain how this approach has been used in KM at Israel Aircraft Industries. Barcelo-Valenzuela, Sanchez-Schmitz, Perez-Soltero, Rubio, and Palma (2008) look at KM for one of the administrative processes of a Spanish university.

Corallo, Lazoi, and Secundo (2012) use a process view of New Product Development to consider knowledge integration in collaborative projects in the Italian aerospace industry, presenting comprehensive recommendations for managers working in similar supply chain contexts, be they prime contractors or lower-tier suppliers. Figueiredo (2013) examines learning and innovation in Motorola’s subsidiary in Brazil. A process approach leads to recommendations about the acquisition, assimilation and internalization of knowledge from elsewhere, whether that is within Motorola or outside it. Hustad (2010) describes corporate memory in a multinational company in the marine insurance industry, and especially how

knowledge is shared across boundaries such as geographical locations, professional specialisms and project teams.

It is becoming more and more common for researchers to take the benefits of a process approach to KM as an assumption. Han and Park (2009, p.7441) observe “[I]f knowledge is separated from the business process context, it does not lead to the ability to take the right action for target performance”. Mas-Machuca and Costa (2012, p.1310) included as an assumption the need “to integrate KM in the business process”. Soares, Santoro, and Baiao (2013, p.1451) state that “An organization that aligns KM with its business process is able to identify gaps, correct mistakes and update more quickly”. Bitkowska (2015, p.54) comments “Knowledge, which is a source of competitive advantage, cannot be considered in isolation from the actions implemented by the company.”

Cao, Thompson, and Triche (2013) recently made a connection not previously observed, by regarding the fit between business processes (task) and KM systems (technology) as an example of the task-technology fit theory, as originally put forward by Goodhue and Thompson (1995), that has found wide application in the information systems field. They find support for better performance from a business processes route in three case studies: a business communication provider, a networking infrastructure solutions provider, and a GPS technology provider.

Although this and many other examples involve substantial use of information technology, that does not have to be the case. The author’s group worked with a component manufacturer in the aerospace industry, whose KM initiative also has an explicit process focus. Typically their manufacturing processes use a machine operated by one person. The operators’ choice of the best way to retain and share knowledge does not use IT at all (except for word processing software and a printer). The agreed best operating procedure,

with illustrations, is put on a laminated sheet of paper mounted near the machine, which includes the names of the people who had contributed to designing the procedure. A suitable pen is provided to annotate the laminated sheet. At regular intervals office staff come round to produce a revised version of any of these “Standard Operating Sheets” that have been annotated.

Most significantly of all in terms of demonstrating the movement of this approach into the mainstream, a survey by the American Productivity and Quality Center (APQC) in 2011 found that more than half of the organizations surveyed were integrating KM into their critical processes and workflows at the enterprise level (Trees, 2011). It is much easier to do this if a business processes perspective is adopted, as shown by two recent studies in Taiwan. Hung, Tsai, Lee, and Chau (2015) demonstrate the mediating effect of business process outcomes between KM enablers (KM infrastructure and KM capability) and KM effectiveness, using data from hospitals and financial services. The assumption that KM needs to be aligned with the business processes is implicit in the way they measure the outcomes (efficiency, effectiveness, flexibility). Wu and Chen (2014) use a similar model on data from the manufacturing sector, with business process capability as the mediating factor between knowledge assets/knowledge process capability and organizational performance.

FUTURE RESEARCH DIRECTIONS

During the 21st century, business processes have become part of the mainstream of management thinking. Strategic management textbooks, e.g. Johnson, Whittington, Scholes, Angwin, and Regnér (2013), now routinely cover the business process view of organizations. As explained in the previous section, over the past 5-10 years it has begun to be accepted that the most effective

way to develop knowledge management in an organization is to integrate it with the organization's business processes.

It seems clear, therefore, that the integration of knowledge management and business processes will become even more common in future, and that this will encourage the development of ever more appropriate information technology for supporting it. Equally, new information technologies will enable new types of process. Social media and smart phones, for example, offer possibilities for the business and for supporting KM which are still only in the early stages of exploitation. They bring challenges, too: for example, unstructured and unrestricted "tagging" of online items may be as much confusing as helpful (Kim, Breslin, Kim, & Choi, 2010). Intelligent agents, wearable devices, and the potential for end-user access to the results of analytics based on big data (especially using new developments in visualization) all present both opportunities and challenges for KM. Perhaps the biggest challenge for integrating KM and business processes remains the need to be able to measure key activities: measurement is at the core of any process approach, but measuring KM is far from easy.

CONCLUSION

This article has considered the implementation of knowledge management in organizations by looking at five different generic routes towards achieving it: knowledge world, functional, IT-driven, people-centric and business processes. While each of these routes has some merit, acceptance is now growing that the business processes route, delivering integration between knowledge management and "what the organization does", is the most effective approach. It is thus likely to be increasingly chosen in the future.

KEY TERMS AND DEFINITIONS

Business Process: A structured, measured set of activities designed to produce a specified output for a particular customer or market (Davenport, 1993, p. 5).

Business Process Reengineering: The fundamental rethinking and radical redesign of business processes to achieve dramatic improvements in critical, contemporary measures of performance, such as cost, quality, service and speed (Hammer & Champy, 1993, p. 32).

Demand-Driven View of Knowledge: A view of knowledge stemming from the requirements of the organization; for example, what knowledge is needed to carry out a particular activity and how can it be applied?

Explicit Knowledge: Knowledge that has been (or can be) codified and shared with others.

Knowledge Management: Supporting and achieving the creation, sharing, retention, refinement, and use of knowledge (generally in an organizational context).

Knowledge Management Software: Software specifically intended for knowledge management, such as data mining and “people finder” software.

Knowledge Management System: A combination of people, processes and technology whose purpose is to perform knowledge management in an organization.

Supply-Driven View of Knowledge: A view of knowledge stemming from the knowledge itself rather than its uses. Often related to a continuum data-information-knowledge.

Tacit Knowledge: Knowledge that is difficult or impossible to express, except by demonstrating its application.

K

Intellectual Capital Measurement

Lukasz Bryl

Poznan University of Economics and Business, Poland

INTRODUCTION

In the contemporary knowledge-based economy the importance of assets related to human, his knowledge and abilities is on the rise. Nowadays Intellectual capital (IC) and intangibles as wealth production factors take precedence compared to physical assets. Especially in the ICT industry, in which Intellectual capital has its origin, IC is perceived as the driver of innovation, growth and competitive advantage of the companies. Moreover in the ICT industry it is the Intellectual capital mostly responsible for the value creation. ICT is being created by Intellectual capital, while at the same time ICT enable efficient Intellectual capital management.

The aim of the article is to present the current state of knowledge concerning Intellectual capital and its measurement methods. Although IC may be identified and calculated on the micro, macro and industry level, this paper deals with the IC measurement on the enterprise level solely. First part of the article is concentrated on the introduction to the IC notion and its main forms, second presents the most common IC measurement methods, while the third part is the analysis of controversies and usability of chosen method to provide a general vision of IC measurement concept.

BACKGROUND

First use of the term *Intellectual capital* took place in 1958 when two financial analysts recognized as the most important element in the information technology companies their *Intellectual capital*. As a result of changes in the structure of econo-

mies in many countries, the term has become a subject of interest and study of a wider group of researchers.

Abeysekera (2006, pp. 61) recognizes Intellectual capital as a form of knowledge that is not posted in the traditional financial reporting. Brooking (1998, pp. 12) believes that Intellectual capital are combined intangible resources that allow organizations to function. Stowe (2001, pp. 86), in turn, argues that Intellectual capital is the ability to use the knowledge possessed by a person or a company to make better use of human and natural resources. In the discussion on the importance of Intellectual capital it is often emphasized that it may have a significant impact on achieving and maintaining a competitive advantage. Stewart (2003, pp. 32) considers the Intellectual capital as a sum of all knowledge the company staff has and what can provide a competitive advantage, manifested in market value which exceeds book value. Edvinsson and Malone (2001, pp. 17) argue that Intellectual capital may be recognized as the difference between the market value and the book value. Intellectual capital may include: patents, processes, people skills and experience, technologies, information about customers and suppliers (Stewart, 1997, pp. 71).

To sum up IC shall be perceived as intangible assets created by human and his knowledge that have not been entirely disclosed in the balance sheet but play a crucial role in the contemporary business environment in terms of enterprises competitive advantage. Moreover, there shall be stated the difference between the commonly used terms of: Intellectual capital and intangibles. IC is a broader notion than Intangibles - Intangibles shall be associated with these knowledge-based

Figure 1. Forms of Intellectual capital (Edvinsson & Malone, 2001, p. 45)

assets that can be reported and valued in the financial statements of the enterprises. In this sense Intangibles are part of IC.

Defining Intellectual capital is a complex activity, as it has several dimensions and may be presented in many ways. Figure 1 provides one of the most common and widely accepted classification of IC.

Intellectual capital has two main forms, which are human capital and structural capital. Human capital includes employee's collective knowledge, competence, abilities and the power of brain. Structural capital, however, is divided into customer capital and organizational capital. Customer capital encompasses relationships with customers, suppliers, industry associations and market channels. Organizational capital, that may be further divided into innovation and process capital, are enterprise policy and procedures, software applications, research and development programs, patents and training courses (Seetharaman, Sooria, & Saravanan, 2002, pp. 130).

Researchers argue that knowledge and consciousness about the IC existence is solely not the ultimate goal of analyzing this complex phenomena. Far more useful is the identification and measurement of IC and its components, as it is crucial for the proper valuation of the enterprises

(especially stock exchange companies). In this sense it helps investors to take strategic decisions concerning portfolio structure. Moreover, proper measurement of IC can provide a better view on the entity assets what plays a significant role in the mergers and acquisition transactions.

The most well-known and at the same time basic classification of measurement methods of Intellectual capital is the division proposed by Sveiby (2001), consisting of four groups:

1. Direct Intellectual capital Methods that focus on the study of certain (chosen) intangible assets.
2. Market Capitalization Methods which are basing on the difference between the market value and the book value, representing the value of Intellectual capital.
3. Return on Assets Methods, which examine the profitability of individual assets (including intangibles) involved in the company during the analyzed period.
4. Scorecard Methods, that, similarly to the direct measurement methods focus on the determination of individual components of Intellectual capital with such a difference that they rarely allow for estimating their monetary value.

Methods described above have been distinguished with the use of two criteria: possibility of IC valuation and measurement level. In that sense Market Capitalization, Return on Assets Methods and Direct Intellectual capital Measurement Methods provide the value of IC, however the first two apply to the organizational level, while the last one allows to identify certain components of IC within an organization. In addition, Scorecard Methods do not provide exact IC value, however they enable the identification of certain IC elements in a given entity.

Although there are more than 40 widely recognized IC measurement methods, due to the limited space, Table 1 provides information only on selected, most renowned methods.

DISCUSSION ON THE INTELLECTUAL CAPITAL MEASUREMENT METHODS

Although, there is a plethora of Intellectual capital measuring methods on the theoretical background, proper IC calculations still cause serious problems and controversies. According to the above mentioned groups, Direct Methods provide data only on chosen IC components and as they do not need to measure IC elements in financial terms, their outcomes are not very useful for financial and comparing purposes.

More holistic approach, and thus better view on IC as an entire resource (capital) attributed to an enterprise provide Scorecard Methods, that

Table 1. Summary of the main Intellectual capital measurement methods

Method	Author, Year	Description
Direct Intellectual Capital Methods		
The Value Explorer	(Andriessen & Tiessen, 2000)	Method distinguishes IC as five types of intangibles: (1) Assets and endowments, (2) Skills and tacit knowledge, (3) Collective values and norms, (4) Technology and explicit knowledge, (5) Primary and management processes.
Intangible Assets Valuation	(Sullivan, 2000)	Methodology concentrating only on the valuation of intellectual property.
Accounting for the Future (AFTF)	(Nash, 1998)	Model is based on future, projected, discounted cash-flows. IC is perceived as Value added that is being estimated as a difference between AFTF at the end and at the beginning of the period.
Inclusive Valuation Methodology (IVM)	(McPherson, 1998)	Final IC value is the combination of Monetary Value Added and Intangible Value Added. Model uses hierarchies of weighted indicators.
Total Value Creation (TVC)	(Anderson & McLean, 2000)	Discounted future cash-flow are used to re-examine the effect of events on the planned activities.
Technology Broker	(Brooking, 1996)	IC is divided into four components: (1) Human-centred Assets, (2) Intellectual Property Assets, (3) Market Assets and (4) Infrastructure Assets. IC value is calculated on the basis of in-depth analysis of answers on 20 questions covering mentioned IC components.
Market Capitalization Methods		
Tobin's q	(Tobin & Brainard, 1968)	The ratio between the stock market value and the replacement cost of its assets. Commonly, formula is presented as the ratio between market and book value. Figures above 1 indicate there is a hidden value (IC) which is not reported in the traditional company accounting.
Market Value Added (MVA)	-	The easiest and most common IC valuation. IC is the difference between current stock market value and its book value.

continued on following page

Table 1. Continued

Method	Author, Year	Description
Investor Assigned Market Value (IAMV)	(Standfield, 1998)	IAMV uses the market value of the company as the true value and divides it into: tangible capital, realized IC, IC erosion and Sustainable Competitive Advantage (SCA).
Return on Assets Method		
Calculated Intangible Value (CIV)	(Stewart, 1997)	CIV is based on the assumption that an enterprise generates IC when its ROA is higher than mean industry ROA; thus showing the capability to generate higher profits with the use of the same tangible assets what is explained by the IC presence.
Human Resources Costing	(Johansson, 1997)	Model concentrates on the impact of human resources on the company performance. IC is calculated as the difference between contribution made by human assets and salary expenditures.
Knowledge Capital Earnings (KCE)	(Lev, 1999)	Financial outcome of the company (net profit/loss) is the result of involving physical, financial and intangible capital. By taking the mean rate of return each of the capital it is possible to estimate the outcome attributed to the intangible capital.
Economic Value Added (EVA)	(Stewart, 1997)	EVA shows if the company generates profits for the shareholders by comparing its pre-tax operating profit with its cost of capital. Useful method for fostering strategic decisions in an enterprise.
Value Added Intellectual Coefficient (VAIC)	(Pulic, 1997)	Divides capital involved in the company into 3 components: physical capital, structural capital and human capital. The efficiency of creating value by each of the components is calculated.
Scorecard Methods		
Balanced Scorecard	(Kaplan & Norton, 1996)	It is a set of indicators referring to four major firm's perspectives: (1) financial, (2) customer, (3) internal process and (4) learning, which are based on strategic objectives of an enterprise.
Intangible Assets Monitor	(Sveiby, 1997)	It is based on estimating the capability of creating value from intangible assets in terms of four indicators: (1) growth, (2) renewal, (3) utilization/efficiency and (4) risk reduction/stability according to the company strategy.
IC-Index	(Roos, Roos, Dragonetti & Edvinsson, 1997)	Single IC index that puts together all indicators referring to the intellectual properties and its components. IC Index values are then compared to the market value changes.
Skandia Navigator	(Edvinsson & Malone, 1997)	One of the first methods; has been developed for the purpose of estimating IC in the Swedish enterprise, Skandia. IC is calculated with the help of 164 indices. 73 are traditional, whereas 91 intellectually based. Together they cover five components referring to the past (financial components), present (customer, process, human) and future (renewal and development). With the help of Skandia Navigator it is possible to distinguish between different forms of IC.
Holistic Approach Value	(Rambøll, 1999)	Model weights nine key areas of corporate performance to give true and fair value of the company. Eight key areas: (1) Values and management, (2) Strategic processes, (3) Human resources, (4) Structural resource, (5) Consultancy, (6) Customer results, (7) Employee results, (8) Results are intangible and measured by the indices that provide information about the true above the market value.

Source: Own work based on <http://www.sveiby.com/articles/IntangibleMethods.htm>

measure IC from the bottom up, can be applied at every level of an organization and provide useful data on firm's IC. However, as Scoreboard methods rely on the contextual and subjective indicators, their meanings may be ambiguous and impossible for inter-industry comparisons. Furthermore, their monetary valuation is not possible, hence they give only a broad image of IC, its components and potential influence on company performance, without indicating exact value. Analyzing one of the Direct Intellectual capital Methods, Intangible Assets Monitor there shall be stated that indices taken into account are subjective, and thus may vary and therefore provide different results. The example of Intangible Assets Monitor is presented in the Table 2.

Another (different) group of IC measurement methods form Market Capitalization Methods and Return on Assets Methods. These methods provide data on the exact IC value. Their main advantages are: relatively simple calculation, no major problems with the acquisition of data and (sometimes) the ability to assess which of the assets (tangible or intangible) bring the most benefits to the company. Moreover, by gathering IC values in a long-term, there is an opportunity

to observe changes in time, what may be useful for the diagnosis of main barriers of the company strategic development.

However, they also have disadvantages. The most common methods are: Tobin's q and Market Value Added (MVA) which is based on the previously mentioned indicator. First one states, that by comparing Market Value with the Book Value (Total equity) in the form of a ratio, there can be determined the IC existence (or lack of existence). When Tobins' q is higher than 1, the company possesses IC. This assumption is highly controversial, since it is based on the efficient market hypothesis. However it should be noted that whether markets are efficient enough to capitalize all disclosed information about IC and how many times a market needs to capitalize it stays unclear (Zavertiaeva, 2016). Secondly it should be stressed that Market Capitalization Methods are only relevant to the public companies that shares are traded on the stock exchange. This causes another problem, which is the high volatility of market value, and thus IC value, since the stock price is the result of daily supply and demand. Another problem is that values received are strongly dependent upon the macroeconomic environment. In the boom

Table 2. The example of intangible assets monitor

Competencies	Internal Structure	External Structure
Growth/Renewal Indices		
• Average professional experience of the employee (years) • Share of the customers increasing the knowledge resources of the company in total sales • total competencies – sum of all professional employee years	• Investments in IT as a percentage of sales • Share of customers strengthening the internal structure in total sales • R&D expenditures as sales percentage	• Company revenue growth • Share of customers strengthening the firm image in total sales
Efficiency Indices		
• Value added per one expert • Value added per one employee	• Changes in the proportion of auxiliary staff to all staff	• Sales per one client
Stability Indices		
• Experts rotation • Average number of working years of the professional staff • Average age of experts	• Employee rotation • Average number of working years of auxiliary staff • Share of employee with the work experience shorter than two years	• Share of regular customers • Share of sales per five largest enterprise customers

Source: Own work based on Sveiby (1997)

period they tend to be overvalued, whereas in the recession – undervalued. Hence to eliminate the influence of stock exchange volatility Tobin's q is being modified to the following formula:where:

MV - market value of shares,
 B_LL - book value of long-term liabilities,
 B_TI - book value of inventories,
 B_CL - book value of current liabilities,
 B_CA - book value of current assets,
 B_TA - book value of total assets.

Numerous studies on Tobin's q ratio have been conducted so far. One of them is the study by Kong, Xiao, and Liu (2010, pp. 6-33). Authors have made research on 313 listed companies on the Shenzhen Stock Exchange and found out that the mean Tobin's q ratio was 1,43 what, according to the theory, constitutes IC presence.

The last recommended method of measuring Intellectual capital among methods based on market capitalization is the IAMV model that formula is following:

CV = value of physical + realized capital + IC erosion +SCA

where:

CV - value of the company
 IC - Intellectual capital
 SCA - Sustainable competitive advantage

Although the formula itself seems to be easy understandable, the most ambiguous term is the notion of *Sustainable competitive advantage* that is explained as the long-term competitive advantage of the firm that is not easily duplicable or surpassable by the competitors and thus allows to perform at a higher level than others in the same industry. This theoretical approach may be, however, calculated in many ways.

Among ROA methods there may be also doubts observed that mainly refer to the subjective taken criteria having substantial impact on the final result of IC values. This notion is especially adequate to the Calculated Intangible Value (CIV) and Knowledge Capital Earnings (KCE) methods. CIV formula, designed by Stewart (1997) for IC calculations may be presented as the ratio below:

Main controversies related to the CIV formula emerge in terms of calculating the discount rate and mean industry ROA. First one seems to be a major problem, since under the term *industry* there should be understood the most similar group of peer enterprises so that the comparison would be legitimated. This occurs to be a problem due to four reasons. First, peer group should derive from possible same industry and country, second, peer group should be quite numerous, third, only companies that provide reliable financial accounting can be taken into account, and fourth, there may be compared entities that are in the analyzed period on the same or similar level of development,

Figure 2. Modified formula for Tobin's Q

$$\text{Tobin's } q = \frac{MA + B_{LL} + B_{TI} - B_{CL} - B_{CA}}{B_{TA}}$$

Figure 3. CIV formula by Stewart (1997)

$$IC_{CIV} = \frac{(\text{Income before Tax} - ROA_{\text{Industry}}) \times (\text{Total assets} - \text{Intangibles}) \times (1 - \text{Tax rate}_{\text{effect}})}{\text{discount rate}}$$

thus peer group may not include large TNC's and SME at the same time.

Furthermore, according to the controversial discount rate assumptions, the most common way of the CIV calculations are based on the weighted average cost of capital (WACC) that consists of: cost of equity and cost of debt. First one is estimated, primarily, by using the Capital Asset Pricing Model (CAPM), that, in its basic form, includes three variables: risk-free rate, risk premium and beta. Not going into detail, on the theoretical and empirical level there is no one clear method of calculating these values, hence the final result of the cost of equity and WACC may be different.

In the research on CIV method Aho, Ståhle, and Ståhle (2011, pp. 27-35) have tested the possible connections of CIV to profitability, market value and different capital assets in firms listed on the Finnish Stock Exchange during 2004-2008. Correlation analysis showed that CIV value is positively associated with the firm's market value and different capital assets, but not with profitability and financial assets.

Second, controversial method among ROA methods is the Knowledge Capital Earnings (KCE), developed by Lev (1999). It assumes that the financial result of the company is due to the use of physical, financial and intangible assets. Taking into account the average rate of return on physical and financial assets, it is possible to determine the earnings attributed to knowledge, and after discounting it - the value of this capital. The formula for KCE is following:

$$\text{Financial result} = \alpha \times \text{physical assets} + \beta \times \text{financial assets} + \delta \times \text{intangible resources}$$

where:

α - return on physical assets

β - the profitability of financial assets

δ - the profitability of intangible assets

KCE relies on the average rates of return on investment in physical, financial and intangible assets. Lev proposes 7%, as a return rate for physical capital investment, what is attributed to the mean rate of return for physical capital in the entire economy. Rate of return for the financial assets is 4,5% which is the average rate of return of 10-year US bonds during 1980-1990. However, the rate of return for intangible assets has been set for 10,5%, which is the average rate of return on stock investments in biotechnology and software enterprises during 1980-1990. What part of the profit is created by the individual types of resources is highly controversial. Moreover, proposed by Levy values for the rates of return seem to be obsolete nowadays, thus nowadays researchers tend to calculate the rates of return on their own using Lev's methodology.

There is also one unique method of IC measurement among ROA methods that is the Value Added Intellectual Coefficient (VAIC) that assesses what is the return on the capital invested in the company. Its high value means that the company uses resources effectively, both tangible and intangible. This also tells how Intellectual capital is able to create value-added (Pulic, 2000, pp. 702-714). In this method capital that is used by the company is divided into physical (employed) capital, human capital and structural capital. The problem with this method is that VAIC does not really show the value of IC, in fact VAIC provides data only on IC effectiveness. The basic estimation in the VAIC method is the calculation of Value Added which is the sum of operating profit (EBIT), amortization/depreciation and human capital. Moreover, it assumes certain values from the traditional accounting as IC or its components. For example human capital (as part of IC) is the total value of human resources expenditures (basic remuneration, performance premium and trainings), whereas structural capital is the difference between value added and human capital. Basing on the above assumptions and provided methodology several studies have been conducted to measure IC effectiveness with the use of VAIC

method. One of them was the study conducted by Ståhle, Ståhle, and Aho (2011, pp. 531 - 551). Authors analyzed 125 listed Finnish companies. The mean VAIC value in 2006-2008 was 2,8%, however mean Value Added amounted to 485 million EUR. Moreover, authors found out that VAIC values were significantly positively correlated with ROA, however there was no relation found between VAIC and Market Value.

SOLUTIONS AND RECOMMENDATIONS

As stated in the beginning, although the notions of IC and intangibles are not the same, they are partly overlapping terms. Thus some part of IC (in form of intangibles) may be valued with the use of traditional accounting tools. Although unambiguous measurement of IC is still a problem, there has been some recognized attempts undertaken for IC components (Intangibles) identification. At the same time many entities gradually adopt international recommendations in terms of intangible assets quantification. According to IFRS 3 there are following intangible assets distinguished (International Financial Reporting Standard Foundation, 2008, pp. 113-118):

- **Marketing-Related**
 - (Trademarks, trade names, service marks, collective marks and certification marks, Trade dress, Newspaper mastheads, Internet domain names, Non-competition agreements);
- **Technology-Based**
 - (Patented technology, Computer software and mask works, Unpatented technology, Databases, including title plants, Trade secrets, such as secret formulas, processes and recipes);
- **Customer-Related**
 - (Customer lists, Order or production backlog, Customer contracts and related customer relationships, Non-contractual customer relationships);

- **Artistic-Related**
 - (Plays, operas and ballets, Books, magazines, newspapers and other literary works, Musical works such as compositions, song lyrics and advertising jingles, Pictures and photographs, Video and audiovisual material, including motion pictures or films, music videos and television programs);
- **Contract-Based**
 - (Licensing, royalty and standstill agreements, Advertising, construction, management, service or supply contracts, Lease agreements, Construction permits, Franchise agreements, Operating and broadcast rights, Servicing contracts, such as mortgage servicing contracts, Employment contracts, Use rights, such as drilling, water, air, timber cutting and route authorities).

These intangible assets might be identified in the company balance sheet, valued and prepared for the potential sale to the third parties. It should be noted that, according to the international standards of accounting, only these components of intangible assets can be reported in the financial statements (Nimtrakoon, 2015, pp. 4). The remaining assets, that individual distinction is impossible, may be subject to sales transactions only within the sale of the whole company. One of such assets is called goodwill, which is defined as a difference between the purchase price of a particular entity or its parts and the fair value of the acquired net assets. As the notion is a subject of discussion Johnson and Petrone (1998) identified following categories of goodwill:

- Excess of the fair values over the book values of the acquiree's reported net assets;
- Fair values of not identifiable intangible assets;
- Fair value of synergies from combining the acquirer's and acquiree's businesses;
- Overpayment by the acquirer.

Studies on goodwill clearly state that it can be demonstrated in terms of accounting standards in the company's balance sheets when the entity is sold for a higher value than the total value of its assets including liabilities. Then the surplus is treated as an additional value and appears on the company balance sheet

FUTURE RESEARCH DIRECTIONS

Current state of knowledge on the IC estimations and tools shows that finding an ultimate and best measurement methods of IC is not a widely accepted and finished process. Although there has been much done in terms of IC identification, there is still a lot of effort needed to establish widely recognized method(s) for calculating its value. Proper procedure for IC valuation shall include following basic features: it shall be comparable in time, among countries and across industry. Moreover, it should be free of any subjective criteria (or at least reduced to the minimum essential), so that IC value could not be questioned because of imperfect methodological assumptions.

CONCLUSION

On the basis of undertaken studies there may be several conclusion formed concerning the problem of Intellectual capital measurement. As a result there can be stated:

- Lack of one widely accepted and universal definition of Intellectual capital,
- Coexistence of the concept of Intellectual capital and value creation term implies the conclusion that Intellectual capital makes sense only if it generates the value growth in the organization,
- Interchangeability of the terms: Intellectual capital, value of intangible, intellectual assets, intangible assets, assets hidden, intellectual resources and intangible resources,
- Intellectual capital provides useful knowledge, with the help of which substantial financial results may be achieved,
- The most common classification of the Intellectual capital is the division on: human, customer and organizational capital. There are tools for valuing each of them,
- Great controversies with the Intellectual capital measurement, as a result of methods diversity and taken assumptions,
- Lack of one widely accepted measurement method of Intellectual capital – urgent need for new tools and procedures.

KEY TERMS AND DEFINITIONS

Book Value: Value of Total Assets less Liabilities.

Customer Capital: Relationships with customers, suppliers, industry associations and market channels.

Efficient Market Hypothesis: Assumption stating that existing share prices always incorporate and reflect all relevant information and thus are traded at a fair value.

Financial Statement: Corporate document presenting company performance during studied

period, typically consisting of: balance sheet, cash-flows and income statement.

Human Capital: Employee's collective knowledge, competencies, abilities and the power of brain.

Intellectual Capital: Hidden intangible assets based on the human knowledge that are not entirely reported in the financial statement of the enterprise and are playing significant role in the knowledge-based economy.

Knowledge-Based Economy: Economy which is directly based on the production, distribution and use of knowledge and information.

Market Value: Value of an enterprise calculated as a number of shares multiplied by unit share price.

Organizational Capital: Enterprise policy and procedures, software applications, research and development programs, patents and training courses.

ROA: Return on assets; the formula is calculated as the ratio of net profit/loss to total assets.

Knowledge Acquisition on Dante Alighieri's Works

Elvira Immacolata Locuratolo

ISTI-CNR, Italy

Valentina Bartalesi Lenzi

ISTI-CNR, Italy

INTRODUCTION

Towards a Digital Dante Encyclopedia is a three-year Italian National Project that aims to build a digital library endowed with services to support scholars in creating, evolving and consulting a digital encyclopedia of Dante Alighieri and of his works (Alighieri, 2011, 2014). Studies concerning the semantic representation of the notes to Dante Alighieri's works can be found in Bartalesi, Locuratolo, Meghini and Versienti (2013). A semantic network of Dante's works and their contextual knowledge is described in Andriani, Bartalesi, Locuratolo, Versienti, Meghini, Tavoni and Versienti (2013).

This article is a research paper related with one of the project objectives, i.e. the identification and the implementation of visualization diagrams to support the of knowledge acquisition on Dante's works. The collaboration between humanists and computer scientists was essential for the purposes of this activity. Moreover, knowledge from humanists was advantageously exploited to individuate the right diagrams; knowledge from computer scientists was advantageously exploited to solve methodological problems of research, implementation and graphical representation.

The approach followed for the purposes of this activity was based on three phases, respectively called identification, implementation and graphical representation. With regard to the identification

phase, two high level structures were introduced: the former, called Dante work's sources, is concerned with the cited primary sources; the latter, called Dante work's structure, is concerned with the structure of Dante's works. For each of them, significant types of histograms were identified. The structure Dante work's sources is applicable to both all the Dante's works/a selected Dante's work. In the former case, the histograms that can be derived from the structure are sufficient to fulfill the project purposes; in the latter case, the histograms derived from both the structures, Dante work's sources and Dante work's structure, need to be related.

The implementation phase is concerned with a table summarizing the structures and the knowledge from humanists. The significant types of citation histograms are represented in a model that does not reduce the completeness of the graphical information. The model is formed by a table containing four columns identified by the 4-tupla (Domain, Range, Graphical Type, Refinement).

With respect to the graphical representation, the histogram is a function depending from the parameters Domain and Range. The domain is represented on the horizontal axis of a cartesian diagram, whereas the citation distributions are represented on the vertical axis. The possibility to refine the acquired knowledge, as well as the possibility to increase it is provided. An examples of citation histograms is given.

BACKGROUND

The study concerning the semantic representation of the knowledge contained in commentaries to Dante Alighieri's works, especially focused on primary sources which are the works of other authors cited by Dante in his texts, is summarized. The approach is composed of several steps: the first step of them started from the analysis of an Excel style sheet, where some pieces of knowledge included in a commentary of *Convivio* (Alighieri, 2014), a philosophical essay composed by Dante Alighieri in the years between 1304 and 1307, were organized and reported by an Italian scholar. In the Excel sheet, every note is given in a row, and is composed of the following pieces of knowledge:

- Number of chapter of the annotated text, represented as a pair of the form book chapter (e.g., 1.01 indicates the first chapter of the first book of *Convivio*);
- Number of the paragraph;
- The text fragment to which the note applies (e.g., “Sì come dice lo filosofo nel principio della Prima Filosofia”);
- The text of the note;
- The last three columns give information about a primary source reported into the note, structured as:
 - Author (e.g. Aristotele);
 - Title (e.g. Metafisica);
 - Thematic area (e.g. Aristotelismo).

In the second step, in order to create an ontology in RDF (Manola & Miller, 2004) for the semantic representation of the previous pieces of knowledge, the terms belonging to vocabularies used in the Digital Libraries domain were identified. For this purpose, several existing ontologies, e.g. CIDOC-CRM (Doerr, 2003), FRBR (Tillet, 2005), FaBiO (Peroni & Shotton, 2012) SKOS (Miles, Matthews, Wilson & Brickley, 2005) were investigated, and the terms that we considered useful to represent

our knowledge were chosen. In order to describe all the knowledge embedded in the commentary, we added classes and properties (Bartalesi, Locuratolo, Meghini & Versienti, 2013).

In the third phase, we built a RDF graph that represents the semantics of the commentary structured according to the ontology. After this preliminary study on commentary to *Convivio*, we used the developed ontology to represent other works of Dante as well as the knowledge carried by commentaries to them. Since the structure of knowledge reported in the Excel file is valid also for other Dante's works (i.e. *Monarchia* (Alighieri, 2014), *De Vulgari Eloquentia* (Alighieri, 2011), and *Vita Nova* (Alighieri, 2011)), the ontology was populated with other knowledge. Three experts extracted the previous reported pieces of knowledge from commentaries to these Dante's works, using a semi-automatic tool we developed. Finally, the RDF graph was stored into a Virtuoso triple store (Erling & Mikhailov, 2009).

The technical advantages of our approach are essentially three: (1) researchers can add classes and relationships to our ontology, thereby refining it, (2) our ontology can be linked to other ontology to extend the represented domain, (3) any user can download and use our model freely, using the paradigm of Linked Data.

Web services were developed to visualize the knowledge stored in the graph in form of charts and tables and CSV format. Using SPARQL query language to extract knowledge from Virtuoso, the services make it possible to address several tasks carried out by the scholars building an encyclopedia of Dante's works, starting with the visualization of the distribution of primary sources both in time and in the works of Dante. The overall goal is to shed light on the cultural context in which Dante wrote his works and on the development of Dante's reference library over time. Our diachronic analysis, in fact, aims at representing the evolution of Dante's knowledge about primary sources.

MAIN FOCUS OF THE ARTICLE

The focus of this article is concerned with one of the main research activity supporting the *Towards a Digital Dante Encyclopedia* project: the approach followed for the identification and the implementation of visualization histograms useful to the digital humanities scholars, during the acquisition of knowledge on Dante's works. Firstly, high level structures are introduced. Secondly, an implementation model is given. Finally, a discussion is provided. The high level structures make it possible to identify the types of significant histograms of all the Dante's works/a Dante work. The implementation model offers the minimal number of histogram types need to preserve completeness. The discussion focuses on educational aspects of mathematics and statistics underlying the histogram representation; on the approach to acquire knowledge on Dante's works starting from the visualization diagrams, and on research advancements. The achievements of the *Towards a Digital Dante Encyclopedia* projects, in particular, the description of the web application development (Le fonti dantesche, n.d.); of the search forms for queries and of histogram examples are provided in (Tavoni, Andriani, Bartalesi, Locuratolo, Meghini & Versienti, 2014).

SOLUTIONS AND RECOMMENDATIONS

In this section, the solution to the identification and implementation of visualization diagrams able to support the knowledge acquisition on Dante's works is proposed. The approach is based on three phases, respectively called identification, implementation and graphical representation.

With regard to the identification phase, two high level structures were introduced: the former, called Dante work's sources, is concerned with the primary sources cited in Dante's works; the latter, called Dante work's structure, is concerned with the structure of Dante's work. For each of

them, the significant types of citation histograms were first identified. The structure Dante work's sources is applicable to both the Dante's works/a selected Dante's work. In the former case, this structure is sufficient to fulfill the project purposes; in the latter case, the histogram types of both the structures Dante work's sources and Dante work's structure need to be related. The two structures are described in the next sections.

Dante Work's Sources

Dante work's sources is a high level structure exploited to identify the histogram types useful to the scholars. The structure is identified by the triple (categories, primary sources, authors). An example of this structure is provided in Figure 1. The label at the highest level is representative of the Dante's works/a selected Dante work.

The labels at the first level represent the categories under which the citations of the Dante's works/a selected Dante work fall. The categories level is organized in sub-categories defining a graph: moreover, the citations that fall under a category can be further broken. Conversely, the citations that fall under sub-categories fall also under a higher category. Thus, the branches of the category tree are oriented from the top to bottom level.

The labels at the level of primary source represent the sources cited in the Dante's texts. The citations that fall under a category/sub-category can be related to more primary sources. In Figure 1, the Aristotelism category is related to both the primary sources *Etica Nichomechea* and *Metafisica*. Conversely, each primary source can fall under many categories/subcategories. As an example, the citations to the primary source *Metafisica* fall under both the categories *Aristotelismo* and *Scolastica*.

Each node at the author level represents the author of one or more primary sources, as an example, *Aristotele* is the author of both the primary sources *Etica Nichomechea* and *Metafisica*, conversely, each primary source has been

Figure 1. Dante work's sources

written by one and only one author; thus, only a link starts from a primary source to its author. Conversely, more links can start from an author to the primary sources.

In order to identify the significant types of histograms, the levels of the structure Dante work's sources are examined moving along the oriented directions of the triple (Categories, Primary sources, Authors). The oriented links are exploited to identify the refinements of the identified histogram types. As an example, if the citation histograms of a Dante's work that fall under categories have been identified, these histograms can be refined into subcategories. The types of citation histograms of Dante's works/a selected Dante's work determined from the structure Dante work's sources are the following:

- Citation histograms that fall under *categories*;
- Citation histograms that fall under *categories* refined in *subcategories*;

- Citation histograms that fall under *categories* refined in *cited primary sources*;
- Citation histograms that fall under *categories* refined in *authors of cited sources*;
- Citation histograms that fall under *sub-subcategories* of a *category*;
- Citation histograms that fall under *sub-subcategories* of a *category* refined in *cited primary sources*;
- Citation histograms that fall under *sub-subcategories* of a *category* refined in *authors of cited primary sources*;
- Histograms to *cited primary sources*;
- Histograms to *cited primary sources* refined in *categories/sub-categories*;
- Histograms to *authors of cited primary sources*;
- Histograms to *authors of cited primary sources* refined in *categories/sub-categories*.

Figure 2. Dante's work structure

Dante Work's Structure

The Dante work's structure is a tree identified by the triple of levels (books, chapters, paragraphs) and by the part of relation, a reflexive, asymmetric and transitive relation, symbolically represented by ($\leq P$). This will mean that the books are part of a work, the chapters are part of a book and the paragraphs are parts of a chapter. The root of the structure represents a Dante's work, as an example the *Convivio* work. Each node of the structure is characterized by an index if the node belongs to the book level, as an example the i^{th} book, two indices, if the node belongs to the chapter level, as an example the j^{th} chapter of the i^{th} book, and three indices if the node belongs to the paragraphs level, as an example the k^{th} paragraph of the j^{th} chapter of the i^{th} book. The tree branches are uni-directionally oriented from top downwards. Figure 2 represents the Dante Work's structure.

The tree levels (books, chapters, paragraphs) are examined moving from the top to the bottom level of the structure; analogous examination is performed for the two level subtrees and for the single level subtrees.

The following are the identified types of citation histograms determined by the Dante work's structure:

- Histograms of citations in the *books* of a Dante work.
- Histograms of citations in the *books* of a Dante works refined in *chapters*.
- Histograms of citations in the i^{th} book of a Dante's work.
- Histograms of citations in the i^{th} book of a Dante's work refined in *chapters*.
- Histograms of citations in to j^{th} chapter of the i^{th} book of a Dante's work refined in *paragraphs*.

In order to complete the list of the possible citation histograms types for a *Dante's work*, the above two sets of histograms have been related as follows:

- Histograms of citations in the *books* of a Dante's work with refinements in *categories/primary sources/authors of primary sources*.
- Histograms of citations in the i^{th} book of a Dante's work with refinements in *categories/primary sources/authors of primary sources*.
- Citation histograms of a Dante's work that fall under *categories/subcategories* with refinements in *books/chapters of the i^{th}*

- *book/ paragraphs of the j^{th} chapter of the i^{th} book.*
- Histograms of citations of a Dante's work to *cited primary sources* with refinements in *books/chapters of the i^{th} book, paragraphs of the j^{th} chapter of the i^{th} book.*
- Histograms of citations of a Dante's work to *authors of cited primary sources* with the refinements in *books/ chapters of the i^{th} book/ paragraphs of the j^{th} chapter of the i^{th} book.*

The Implementation Phase

The implementation phase is concerned with a table containing four columns identified by the 4-pla (Domain, Range, Graphical Type, Refinement). This table summarizes the high level structures and the knowledge from humanists. The significant types of citation histograms are represented in a minimal model that does not reduce the completeness of the graphical representations. The minimal model is not-unique.

In the first rectangle of the *Domain* column, the following options, related to the root of Dante work's source and to Dante work's structure can be chosen:

- Dante's works involving the set of all the Dante's works;

- Dante work involving a selected work of Dante;
- Part of Dante work involving a part (book, chapter, paragraph) of a Dante's work.

The same options can also be chosen in the second, in the third and in the fourth rectangles of the Range column. In the second rectangle of the Domain column, the following options, related to the former level of the Dante work's source, can be chosen:

- Categories involving the set of all the categories under which the citations can fall;
- Category involving a selected category;
- Sub-category involving a part of a selected category.

In the third and in the fourth rectangles of the Domain column, the following options, respectively related to the second and third level of the Dante work's source can be chosen:

- Primary sources involving the works cited by Dante in his works;
- Authors involving the authors of the cited works.

The options of Categories, Primary Sources and Authors proposed in the second, in the third

Table 1. The minimal model

Domain	Range	Graphic Type	Refinements
<i>Dante's works</i> <i>Dante work</i> <i>Part of Dante work</i>	<i>Categories</i> <i>Category</i> <i>Sub-categories</i>	→ 2 → 3 → 4	→2 in sub-categories → 3 in parts → 4 in works
<i>Categories</i> <i>Category</i> <i>Sub-categories</i>	<i>Dante's works</i> <i>Dante work</i> <i>Part of Dante work</i>	→ 5	→5 in parts
<i>Primary Sources</i>	<i>Dante's works</i> <i>Dante work</i> <i>Part of Dante work</i>	→ 6	→6 in parts
<i>Authors</i>	<i>Dante's works</i> <i>Dante work</i> <i>Part of Dante work</i>	→ 7	→7 in parts

and in the fourth rectangles of the Domain column are the same of the first rectangle of the Range column. The graphical types of histograms and their refinements are summarized in the third and in the fourth column of the table. If the Dante's works option is selected, no refinement is possible; otherwise, refinement by parts is always possible. Further, if the option categories is selected, a possible refinement is in sub-categories. Analogously, if the option author is selected, the histogram can be refined in works.

The graphical representation of the citation histograms is a function depending from the parameters Domain and Range, i.e., Graphic (Domain, Range). An option is selected for both the component of the couple (Domain, Range), as an example, Graphic (Convivio, Philosophy). In this case, the result of the function is a citation histogram enclosing the Convivio books on the horizontal axis; the distribution of the citations that fall under the Philosophy category on the vertical axis. The histogram can be refined as an example in chapters. Another possible refinement is for example in sub-categories. In Figure 3, the citation histogram of the proposed example is provided.

Further advancements of this work were concerned with the possibility to increase the knowledge acquired by the scholars with respect to other parameters, as an example the time parameter; thus, knowledge can also be extracted according to chronological order.

DISCUSSION

Statistical analysis is generally based on data proposed in tables or in visualization diagrams. In this chapter, data visualized through histograms are the starting point to support the scholars in the acquisition of knowledge on Dante's works. In order to explain how knowledge can be acquired, let us start from the function: Graphic (Domain, Range), in mathematics $f(x,y)$. For each couple of values, one for the Domain component and one for the Range component, one and only one histogram is returned. In Figure 3, the chosen values are: (Convivio, Philosophy) and the result of the Graphic (Convivio, Philosophy) function is a histogram. The histogram is visualized on a Cartesian diagram; on the horizontal axis, the four Convivio books are represented. The indices $n_1, \dots, n_4$ are the histogram bar heights. For the purposes of this discussion, it is not necessary to have the real citation distribution. The example evidences that all the Convivio chapters cite primary sources that fall under the Philosophy category, but that the citation distribution changes with the chapters. The possibility to refine the histogram exploiting one of the possible refinements proposed in Table 1 is also provided; for example, the citations falling under the Philosophy category can be refined in sub-categories represented by different colours. Let us now suppose that the former component of the couple (Domain, Range) is fixed to the Convivio value, and let us change only the latter

Figure 3. Citation histogram and refinement

component. In this way, the histograms of the *Convivio* books that cite primary sources falling under different categories, Philosophy, Bible, Aristotelism, are returned to the scholars. Comparisons among the obtained histograms give rise to data from which knowledge can be derived.

For advancement: Let us suppose that the former component of the couple (Domain, Range) is represented by intervals of time, in statistics temporal classes; and that the latter component is fixed to the Philosophy category. In this example, the intervals of time are represented on the horizontal axis of the Cartesian diagram, and the numbers of citations that fall under the chosen category are represented by the histogram bar heights. The histogram evidences the variability in time of the Dante's works citations that fall under the Philosophy category. Let us now suppose that other categories are chosen and that new histograms are returned to the scholars. Different types of comparison can be performed among histograms. Knowledge concerning the evolution in time of Dante's cultural background is an example of knowledge that can be derived following this approach.

FUTURE RESEARCH DIRECTIONS

The methodology and the tools developed within the *Towards a Digital Dante Encyclopedia* project can be easily reusable to represent the primary sources of other authors of the Italian or International Literature, different from Dante Alighieri. Future work is concerned with:

- The evaluations of the representational adequacy of the ontology by scholars, expert of Dante Alighieri's works;
- The usability of the implemented Web services through user tests.

The collaboration between humanists and computer scientists is worthy for possible future projects.

CONCLUSION

A research article related with one of the main activities of the *Towards a Digital Dante Encyclopedia* project is presented. The focus is on the identification and the implementation of visualization diagrams to support the knowledge acquisition on Dante's works. The approach proposed to achieve this objective is based on three phases. Two high level structure; an implementation model and a discussion are proposed within these phases. An example of citation histogram and refinement is provided. As achievements of this project, a web application to support scholars in writing a complete encyclopedia on Dante Alighieri was developed. The knowledge included in the semantic network concerning Dante's works can be extracted, and according to different parameters (chronological order, type of source, works, etc.) data about primary sources cited by Dante can be visualized. Conflicting aspects of Dante's biography and evolution in time of its culture can also be explored.

ACKNOWLEDGMENT

The authors thank Prof. Mirko Tavoni and Dr. Paola Andriani – Pisa University; Dr. Carlo Meghini and Loredana Versienti – CNR, for the useful collaboration during the project. A thank to Dr. Paola F. Canonico and to Dr. Andrea Vannozzi for the technical realization of the figures in this article.

KEY TERMS AND DEFINITIONS

Dante Work's Source: High level structure representative of the *Dante's works/a selected Dante's work*. The structure is identified by the labels of the triple (*categories, primary sources,*

authors) and by bi-oriented links relating the labels from one level to another. One and only one link starts from a label at the *author* level to a label at the *primary source* level.

Dante Work's Structure: Tree identified by a *root*, representative of a Dante work, by the triple of levels (*books, chapters, paragraphs*) and by the part of relation, symbolically represented by ($\leq P$).

Digital Humanities: Digital humanities is an area of research and teaching at the intersection of computing and the disciplines of the humanities.

Linked Data: Linked Data describes a method of publishing structured data so that it can be interlinked and become more useful through semantic queries.

Ontology: Is a model for describing the world that consists of a set of types, properties, and relationship types.

Semantic Web: The Semantic Web is an extension of the Web through standards by the World Wide Web Consortium (W3C). The standards promote common data formats and exchange protocols on the Web, most fundamentally the Resource Description Framework (RDF).

Knowledge Management for Development (KM4D)

Alexander G. Flor

University of the Philippines, Philippines

INTRODUCTION

Knowledge management, as a discipline, was borne out of the need to systematically leverage the intellectual assets of an organization to achieve corporate goals. We can trace its origins to Nonaka and Takeuchi's treatise on the knowledge creating company (1995), which was informed by the tacit-explicit knowledge dichotomy of Polanyi (1967). However, it was Davenport and Prusak (1997) who introduced the term knowledge management to the wider management science community.

At the very onset, knowledge management was intended as a tool for the private sector, a means to increase an organization's IQ, as Bill Gates (1999) puts it. Soon after its introduction to the corporate world, however, it was embraced by both the government sector and the international development assistance community owing to the fact that governments and international agencies are, by nature, knowledge organizations. These include United Nations agencies; international financial institutions such as the World Bank, the International Monetary Fund (IMF) and the International Fund for Agricultural Development (IFAD); regional financial bodies such as the Latin American Development Bank, the Asian Development Bank and the African Development Bank; and bilateral aid agencies as well, such as USAID, AusAID, CIDA, JICA, AFD, DFID and others.

Considering the urgent nature of the societal problems addressed by this area, the emphasis of the KM4D community for the past twenty-five years has been on practice rather than on research or theory building. There have been attempts to define the field, but the desirability of a grounded

approach to the discourse necessitated sound referents found in its practice. Thus, even academic journals devoted to this area (e.g., KM4D Journal) focused on field practice documentation and evaluation. Nevertheless, an attempt at defining KM4D by differentiating it from conventional KM can serve as a starting point of theory.

It is the intention of this chapter to differentiate corporate KM from KM4D. It enumerates KM4D sectors and themes used by the international development assistance community in the past two and a half decades. Furthermore, the chapter attempts to present a proto-typology of corporate KM and KM4D for purposes of future theory building and of thickening the knowledge management discourse.

BACKGROUND

Among the first to apply knowledge management to the development agenda and the public sphere was Stephen Denning, who headed the Knowledge Management Program of the World Bank. Denning (2000) employed a technique which he calls organizational storytelling to champion KM among his colleagues. He presents the beginnings of the KM4D narrative in the following account:

As a manager in the World Bank in 1996, I had been trying to communicate the idea of knowledge management and to get people to understand and to implement it. At that time in that organization, knowledge management was a strange and generally incomprehensible idea. I used the traditional methods of communicating with no success... In

my desperation, I was willing to try anything and eventually I stumbled on the power of a story, such as the following: "In June 1995, a health worker in a tiny town in Zambia logged on to the website for the Center for Disease Control in Atlanta Georgia and got the answer to a question on how to treat malaria....

This was June 1995, not June 2001. This was not the capital of Zambia but a tiny place six hundred kilometers away. This was not a rich country: this was Zambia, one of the poorest countries in the world. But the most important part of this picture for us in the World Bank is this: the World Bank isn't in the picture. The World Bank doesn't have its know-how accessible to all the millions of people who made decisions about poverty. But just imagine if it had... This story had helped galvanize staff and managers to imagine a different kind of future for the organization and to set about implementing it. Once knowledge management became an official corporate strategy later that year, I continued to use similar stories to reinforce and continue the change. The efforts were successful: by 2000, the World Bank was benchmarked as a world leader in knowledge management. (Denning, 2000)

There is reason to believe that the roots of knowledge management in the public sphere extended before Nonaka and Takeuchi. It may be traced to a group of pre-World War II Austrian academics who represented a school of thought, known as knowledge economics. Its luminaries were Hayek (1937) and Schumpeter (1942). The movement situated knowledge as a major economic variable but it was overshadowed by the Keynesian school, which dominated post-Bretton Woods economic theory and practice. In the sixties, it was resurrected in the United States by Machlup (1962) and later on by Porat (1978) albeit under a new brand, information economics. It was Machlup and Porat who introduced the Agricultural-Industrial-Information Age(s)

trichotomy as well as the concept of information economy or information society.¹

The KM4D discourse is likewise premised on the pitfalls of mishandling knowledge when it is not distinguished from information or wisdom, in part inspired by the T.S. Elliot poem, *The Rock*, a stanza of which reads:

Knowledge of speech, but not of silence

Knowledge of words, and ignorance of the Word

All our knowledge brings us nearer to our ignorance

All our ignorance brings us nearer to death

But nearness to death, no nearer to God

Where is the life we have lost in living?

Where is the wisdom we have lost in knowledge?

Where is the knowledge we have lost in information?

MAIN FOCUS OF THE CHAPTER

Differentiations

Paraphrasing Leibmann (1999), knowledge management is a nascent or newly emerging discipline that considers an organization's intellectual capital as a manageable and potentially profitable asset. Each and every organization possesses intellectual capital that may purposively be employed to achieve organizational goals, objectives, or targets. Currently, this intellectual capital can be managed mainly through the use of information and communication technology. Gates (1999) uses the digital nervous system metaphor, comparing an organization to an organism with a nervous system technologically enabled by computer

hardware, software and networks. This network of workstations and servers (known as a KM system) programmed to facilitate knowledge sharing and reuse is, to an organization, what a nervous system is to an organism.

Knowledge management for development or KM4D also considers intellectual capital as a manageable asset but it is leveraged not to increase profit but to further the development agenda. KM4D is likewise founded on knowledge science and knowledge economics. It is similarly anchored upon Davenport and Prusak's KM theory and thus adopts a digital environment. However, it is applied within the development context and targeted at the achievement of national, regional or global development goals.

From the point of view of governments and development assistance agencies, knowledge management need not be exclusively applied to organizations. It can very well be employed to non-going concerns such as projects and to larger systems, communities, or development sectors. For instance, knowledge within academia, scientific circles, or communities of practice, can be managed, particularly so with social media and content management systems.

A Prototypology

How exactly does KM4D differ from conventional KM?

Based on twenty-five years of KM4D practice among international development agencies, one can differentiate conventional KM from KM4D in terms of the following: purpose; considerations; thrust; levels of utilization; system functionalities and applications; and system content.

The purpose of conventional KM is economic in nature, specifically the creation of wealth using intellectual assets. It may be said that the purpose of KM is to enhance a company's ability to conduct its core business. Assuming that corporations are primarily profit-oriented, it may be assumed that the end goal of KM is to increase the company's

bottom line. On the other hand, KM4D owing to its origins in the international development assistance sector has always been linked to development goals. From 2000 to 2015, these were called the Millennium Development Goals or MDGs. The MDGs were restructured into what is now known as the Sustainable Development Goals or SDGs for the 2015 to 2030 timeframe. Both the MDGs and SDGs will be discussed in a separate section in this chapter.

In terms of primary considerations, conventional KM guards intellectual assets closely and is geared at managing these assets efficiently. Thus, intellectual property, security of and accountability for these assets figure prominently in its list of considerations. However, KM4D believes in the synergistic or non-zero-sum nature of knowledge. Hence, knowledge is non-proprietary and is considered as a free commodity to be shared openly.

This leads to the concept of knowledge sharing and reuse, the primary goal of knowledge management as proposed by Leibmann (1999). For conventional KM, knowledge sharing and reuse is encouraged freely within the corporate organization but rarely outside it. In KM4D, the parameters of knowledge sharing and reuse extend beyond the organization to all sectoral stakeholders. The thrust of conventional KM is internal knowledge sharing. The thrust of KM4D is external knowledge sharing.

This difference is seen in the design and utilization of KM and KM4D systems. Content of conventional KM systems tends to be demand driven while the content of KM4D systems is supply driven. The former is determined by organizational requirements while in the latter, affirmative action is taken to supply knowledge and information needs of stakeholders. Conventional KM systems are primarily for corporate use of a going concern. On the other hand, KM4D systems may be designed for use at the project level, the agency level, even the sectoral or thematic level. Traditionally, users of KM systems are communities of practice or CoPs. Users of

KM4D systems involve communities of interest (CoIs) and communities of champions (CoCs). Lastly, KM4D systems go beyond conventional messaging and collaboration, file sharing, content management and search functionalities but extend to online learning.

Thus, we arrive at the following proposed typology of conventional KM and KM4D highlighting their differentiations:

Information Technology and Knowledge Management

Intellectual capital comes in two forms: explicit knowledge and tacit knowledge. Explicit knowledge is documented and easily made available in operations manuals, research studies, reports and journals. On the other hand, tacit knowledge is more difficult to manage, because it resides inside a person's head. This, in fact, is the traditional view of knowledge science: that knowledge resides within individuals and thus cannot be effectively managed. As Sarkar (1980) aptly puts it,

knowledge begins with perception and ends with realization. In other words, it requires subjectivization, the conceptual union of the subject (or the knower) and the object (or the known).

Nonaka and Takeuchi (1995) believe that in knowledge organizations, tacit knowledge should be converted to explicit knowledge for it to become a manageable asset. Gates (1999) asserts that information technology has facilitated the digital capture of tacit knowledge and thus enabled its sharing and reuse. Prior to the development of information technology, intellectual capital was considered difficult to manage because tacit knowledge, in particular, primarily resides in the individual. A research organization can lay claim to a paid individual's time or even skills. But it cannot ordinarily share ownership of an individual's knowledge permanently unless it is documented and copyrighted by the organization, which is relatively rare. With information technology, such knowledge can be captured, stored and shared electronically, in short, managed. In its electronic form, knowledge becomes part of content.

Table 1. Prototypology of conventional KM and KM4D

	Conventional KM	KM4D
Purpose	To increase company's bottom line To enhance company's ability to conduct its core business	To further development goals
Considerations	Security and accountability	Synergy
Sharing Parameters	Within the organization	All development stakeholders
Thrust	Internal knowledge sharing (within the company)	External knowledge sharing (for project/agency beneficiaries and other stakeholders)
Content	Demand driven	Supply driven
Levels of Utilization	Organizational level Among communities of practice (CoPs)	Project level Agency level Sectoral level Thematic level Among communities of interests (CoIs) Among communities of practice (CoPs) Among communities of champions (CoCs)
System Functionalities/ Applications	Messaging and Collaboration File sharing Documents/content management Search	Messaging and Collaboration File sharing Documents/content management Search Online learning

FUTURE RESEARCH DIRECTIONS

Knowledge management research may be categorized as thematic or sectoral. By 2005, the international development assistance community had seen it fit to classify development programs under two major categories: sectors and themes. Sectors include agriculture, health, education, environment, natural resources and others. Themes involve crosscutting concerns such as governance, gender, poverty, sustainability, and climate change. KM4D likewise adopts these sectors and themes.

KM4D interventions and, subsequently, research were designed and implemented to contribute to long-term targets of any one of the eight Millennium Development Goals or MDGs:

- **MDG 1:** Eradicate extreme poverty
- **MDG 2:** Achieve universal primary education
- **MDG 3:** Promote gender equality and empower women
- **MDG 4:** Reduce child mortality
- **MDG 5:** Improve maternal health
- **MDG 6:** Combat HIV/AIDS, malaria and other diseases
- **MDG 7:** Ensure environmental sustainability
- **MDG 8:** Global partnership for development

Identified during the Millennium Summit of 2000, these goals were expected to be achieved by 2015. By the beginning of 2015, it has become clear that the MDGs will have to be replaced by a new set of goals, now called Sustainable Development Goals of SDGs. The list has been expanded from eight (8) MDGs to seventeen (17) SDGs:

- **SDG 1:** End poverty in all its forms everywhere
- **SDG 2:** End hunger, achieve food security and improved nutrition and promote sustainable agriculture

- **SDG 3:** Ensure healthy lives and promote well-being for all at all ages
- **SDG 4:** Ensure inclusive and equitable quality education and promote lifelong learning opportunities for all
- **SDG 5:** Achieve gender equality and empower all women and girls
- **SDG 6:** Ensure availability and sustainable management of water and sanitation for all
- **SDG 7:** Ensure access to affordable, reliable, sustainable and modern energy for all
- **SDG 8:** Promote sustained, inclusive and sustainable economic growth, full and productive employment and decent work for all
- **SDG 9:** Build resilient infrastructure, promote inclusive and sustainable industrialization and foster innovation
- **SDG 10:** Reduce inequality within and among countries
- **SDG 11:** Make cities and human settlements inclusive, safe, resilient and sustainable
- **SDG 12:** Ensure sustainable consumption and production patterns
- **SDG 13:** Take urgent action to combat climate change and its impacts*
- **SDG 14:** Conserve and sustainably use the oceans, seas and marine resources for sustainable development
- **SDG 15:** Protect, restore and promote sustainable use of terrestrial ecosystems, sustainably manage forests, combat desertification, and halt and reverse land degradation and halt biodiversity loss
- **SDG 16:** Promote peaceful and inclusive societies for sustainable development, provide access to justice for all and build effective, accountable and inclusive institutions at all levels
- **SDG 17:** Strengthen the means of implementation and revitalize the global partnership for sustainable development

The intention now is to leverage the collective knowledge of the international development assistance community for achieving these goals by 2030. How this can be effectively and efficiently done should be the subject of extensive research within the academic community shaping the KM4D discourse.

CONCLUSION

Knowledge management began in the private sector but has since been adopted by governments and international development agencies alike. In the mid-nineties, Stephen Denning established the Knowledge Management Program of the World Bank, which has served as the model for applying KM to international development assistance or KM4D. In defining KM4D, this chapter reflected the need for a grounded approach by using field practice experience to differentiate corporate KM from KM4D.

The chapter argues that conventional KM and KM4D differ in terms of purpose, considerations, thrust, levels of utilization, system functionalities and applications, and system content. It concludes that KM4D research can best be classified under sectors and themes used by the international development assistance community in the past two and a half decades.

KEY TERMS AND DEFINITIONS

Communities of Champions (CoC): Online as well as offline social networks who advocate a specific development policy, strategy or intervention. These advocates are often the *de facto* spokespersons of stakeholders in the development process.

Communities of Interest (CoI): Networks of persons interested in a common problem who bond together online as well as offline.

Communities of Practice (CoP): Online as well as offline social networks who share a passion for a practice. Their practice improves with regular online and offline interactions as theorized by Lave and Wenger (1991).

Development Stakeholder: Roughly categorized as funding agencies, government agencies, nongovernment organizations (NGOs), civil society and beneficiaries of development aid.

Knowledge Management (KM): An emerging discipline that treats intellectual capital as an asset that may be managed through information and communication technologies.

Knowledge Management for Development (KM4D): Undertakings, systems and products that leverage intellectual capital in the pursuit of national, regional or global development goals.

Prototypology: A prototype typology that is used as an initial device in the theory building process.

ENDNOTE

- ¹ Defined as a society whose economy is information based, i.e. the majority of its workforce is made up of information workers or the greater part of its GNP may be attributed to information products, services and labor (Porat, 1978).

Knowledge Management From the Metaphorical Perspective

K

Magdalena Bielenia-Grajewska
University of Gdansk, Poland

INTRODUCTION

The purpose of this chapter is to present the notions connected with how knowledge management is communicated. The focus of investigation is on the place of metaphors in creating, acquiring and sharing data. The metaphorical side of knowledge management is discussed from both theoretical and practical perspectives. Thus, selected theories are supported with practical examples coming from diversified sources on knowledge management. The discussion aims at showing the positive and negative role of metaphors in various stages of knowledge management.

BACKGROUND

The way knowledge is coded and decoded has changed throughout centuries. Nowadays we can observe the growing role of technology in creating and sharing knowledge in educational (e.g. Turula, Mikołajewska & Stanulewicz, 2015) and professional settings (Bielenia-Grajewska, 2016). Thus, traditional ways of accessing and using knowledge are supported, and in some cases substituted, with virtual sources of data. Apart from the plethora of knowledge resources, the phenomenon of knowledge poverty resulting from limited or no access to information still exists. There are different types of knowledge poverty that can be categorized by taking into account such notions as purpose, target audience,

and form of dissemination. Thus, the following typology of knowledge poverty can be applied: scientific knowledge poverty, everyday knowledge poverty, professional knowledge poverty, social knowledge poverty, cultural knowledge poverty and linguistic knowledge poverty. The last type of knowledge poverty can be understood in at least two ways. First, linguistic knowledge poverty may be represented by no or limited familiarity with the official language spoken in a country one has to study or work in. The second type of linguistic knowledge poverty is connected with the minor positions of some languages or dialects in a given community (Bielenia-Grajewska, 2015b). Another phenomenon connected with restricted understanding and using knowledge is attention crash, represented in limited concentration resulting from information overload. It can be observed especially among people exposed to many impulses (mainly of a technological nature) at the same time. Nowadays this phenomenon is associated with constant access to emails, sms, chatting and talking on the phone (Bielenia-Grajewska, 2014b). One method of dealing with attention crash and knowledge poverty is to handle proper and effective communication. In addition, the linguistic turn in knowledge management is connected with the dynamic character of knowledge. For example, Wittgenstein (1992) highlights that it cannot be determined how long knowledge, skills and understanding last. Consequently, the character of knowledge management (KM) requires proper linguistic forms that will facilitate the process of

perception, comprehension and dissemination of new concepts (Bielenia-Grajewska, Carayannis & Campbell, 2013b).

LANGUAGE AND KNOWLEDGE

Recent publications written by the representatives of different studies draw the attention of readers to the discursive dimension of knowledge management. An example of such domains is discursive psychology. As Crane (2016) discusses in her contribution, interaction is crucial in knowledge creation and knowledge sharing. Thus, talk and text play an important role in KM. The narrative side of knowledge management is also stressed by Schreyögg and Koch (2005) who elaborate on the issue of narration and storytelling as well as their place in KM. In addition, the link between language and culture is discussed by researchers including Holden and Glisby (2014).

The functionality of language in knowledge management can be discussed through the prism of micro, meso and macro perspectives. Starting with the micro approach, language is applied to denote a new concept or a novel idea. The meso level is represented by the usage of linguistic tools in shaping texts. As far as the macro level is concerned, language is also used as a tool facilitating knowledge flows between different domains (Bielenia-Grajewska, 2012). It should also be highlighted that language and knowledge management do not exist in a vacuum; they shape and simultaneously they are shaped by other domains. An example is education - modern education differs from that which could be observed some years ago as teaching and learning of the twenty-first century involve not only various learners in terms of their age, gender and background, but also diversified methods of encoding and decoding knowledge. For example, with the appearance of MOOCs and other educational offers available online, modern education is not as restricted in terms of geography, prior levels of knowledge or types of accessible educational tools as it was

before. Consequently, knowledge is also gained in activities that were previously associated exclusively with the ludic character of our life. An example is the application of serious games in learning (e.g. Bielenia-Grajewska, 2016).

The way language facilitates knowledge management can also be discussed by taking into account literal and non-literal language. Focusing on the complexity of figurative language and its multidimensionality, symbolic communication in KM is given a detailed study in this contribution.

METAPHORS

The purpose of metaphors is to make people perceive one sphere of experience in terms of another, whereas cross-domain interconnections facilitate the observation of similarities between two domains within a given metaphor (Lakoff & Johnson, 2003). Metaphors are used in different domains of life, including, among others, investment banking (Bielenia-Grajewska, 2009), leadership (Lancaster, 2015), neuromanagement (Bielenia-Grajewska, 2013a), translation (Guldin, 2016) and biology (Boldt, 2016). The functions of metaphors are as follows. First, they are efficient in denoting novel objects or phenomena. An example is the area of investment banking, characteristic of new terms describing such economic notions as new strategies of mergers and acquisitions or derivatives (Bielenia-Grajewska, 2009). In other words, symbolic language facilitates the process of introducing new products or services, providing efficient linguistic tools to accompany economic or technological development (Bielenia-Grajewska, 2012). Their “freshness of expression”, novelty in form, makes them popular in coding and decoding different forms of knowledge. Wittgenstein (1992) underlines that a new word is like a fresh seed thrown in the soil of discussion. In the case of KM, new terms coined in professional settings may enrich specialized knowledge and they should facilitate communication between laymen and professionals. Moreover, metaphors are useful in

handling risk communication; they can be used to discuss e.g. food-borne diseases (Bielenia-Grajewska, 2015c). It should also be mentioned that metaphors are not passive communication tools; linguistic symbols construct the reality, imposing a given perspective (Kövecses, 2015). Moreover, Wittgenstein (1989) compares words to acorns from which an oak tree may grow. This comparison may be used to discuss the place of metaphors in KM discourse. Symbolic language, if used effectively, can facilitate an understanding of novel domains as well as coding and decoding new data. Metaphors can be used in business education, to transfer new knowledge from professors to students or from experts to laymen. An example is the usage of metaphorical names relying on the domain of gold to denote the names of participants, instruments and strategies of the modern economic discourse (Bielenia-Grajewska, 2015d). The metaphorical names include golden coffin, golden hello, golden umbrella or golden parachute. The next important feature of symbolic language is its attractiveness; metaphorical names draw one's attention more easily than literal expressions (Charteris-Black, 2007). For example, such M & A (mergers and acquisitions) strategies as black knight or porcupine defense sound more attractive for laymen than their non-figurative descriptions. Another key feature of metaphors is their contextuality (Kövecses, 2015). Metaphors do not exist in a vacuum; they reflect the reality they are part of. The next key issue is the economical character of symbolic communication. In comparison with standard elaborate definitions, metaphorical names occupy (in most cases) up to two words. This feature is especially important in headlines or sneak peaks. Applying metaphors in the discussion on knowledge can also facilitate an understanding of knowledge as a complex concept. Bratianu (2015) in his contribution discusses such examples as *knowledge as energy*, and related subcategorizations, such as cognitive knowledge as a mechanical energy, emotional knowledge as a thermal energy and knowledge dynamics as energy thermodynamics. The functionality of

metaphors in knowledge management can also be discussed through the lens of deliberateness. The purposes and conscious usage of metaphors in KM can be studied from the perspective of Deliberate Metaphor Theory, stressing the non-automatic and intentional use of symbolic language in modern communication, for example, in journalism (Steen, 2015).

Modern contributions on knowledge also stress the role of identity in different stages and methods of KM, especially in technological settings. The growing role of virtual education is also described in new contributions devoted to the role of symbolic language in learning outside the regular classroom. For example, Ligorio, Iodice and Manca (2016) discuss how metaphors not only stimulate knowledge enhancement in virtual settings, but also build a common identity of online learners.

Technology has also influenced the way we perceive the surrounding reality and ourselves. For example, Carr (2016) draws our attention to the way the metaphorical perception of memory has changed. In the past, bees and nectars were used to depict the relation between memory and intellect (e.g. Seneca), whereas nowadays computers and database are used to mirror the above-mentioned relation.

Metaphors and Organizations

The dialogic character of modern organizations is discussed in different contributions (e.g. Bushe & Marshak, 2015), including the knowledge perspective. Organizational knowledge is defined by Bratianu (2015) as the concept encompassing cognitive, emotional and spiritual knowledge (the triple helix metaphor). The linguistic dimension of companies and institutions with regard to KM is created and exercised largely by symbolic language. Metaphors play different functions in organizational communication. First, they are used to stress organizational culture. An example is the study conducted by Bielenia-Grajewska on companies operating in the food industry. This

research has shown that such organizational metaphors as organization as a teacher, organization as a network, organization as a protector, organization as a traditionalist, organization as a travel guide, and organization as a family are used by companies to depict their activities and policies (Bielenia-Grajewska, 2014a). Other contributions (e.g. Zamparini & Lurati, 2016) stress the role of multimodal metaphors in shaping company identity. Since organizations do not only produce or offer services but also knowledge that accompanies their merchandise, metaphors can be used to make their products or services more visible on the competitive market. Organizational innovations are often accompanied by metaphorical slogans or pictorial metaphors to draw the attention of potential stakeholders.

Functions of Metaphors in Knowledge Management-Stage Perspective

The functions of metaphors in different knowledge processes can be discussed by taking into account the key characteristics of different stages connected with managing knowledge. The most representative features are presented by using the Four-dimensional model of metaphorical KM communication (Figure 1), focusing on knowledge management and the place of metaphors in it. The discussion is an enhanced version of the one presented in Bielenia-Grajewska (2015a).

Metaphors and Knowledge Creation

Metaphors turn out to be efficient in the first stage of knowledge management, mainly, in creating novel data and information. Their efficiency and simplicity often result in a better understanding of concepts among specialists working on new approaches or products. Taking into account heterogenic working groups (constituting people representing different professions and educational

Figure 1. Five-dimensional model of metaphorical KM communication (created by the current author)

backgrounds), symbolic language facilitates effective communication, especially when highly specialized notions and technical data are involved.

Metaphors and Knowledge Encoding

Knowledge creators should find relevant tools and channels for encoding novel data. Metaphors play an important role in putting new ideas into linguistic representation known and understood by a large number of users who differ in terms of their professional knowledge, age or educational background.

Metaphors and Knowledge Decoding

Bailin and Grafstein (2016) discuss the role of metaphors in text readability, analyzing such notions as the time needed to decode symbolic messages, in comparison with literal communication. It should be mentioned, however, that some researchers underline the potential negative side of using metaphors in knowledge decoding. Since metaphors rely on one's individual understanding, it may lead to the misinterpretation of information.

For example, the substitution of real numbers with metaphorical names to depict contagious diseases may lead to the wrong perception of risk.

Metaphors and Knowledge Application

Metaphors are used in applying knowledge since they make complex ideas easier to implement when the explanation is supported with concepts coming from well-known domains. It is especially important when knowledge is applied for users who do not possess things like professional or technical expertise or when individuals differ as far as their educational background is concerned.

Metaphors and Knowledge Sharing

This function of metaphors is visible in offering quick and efficient knowledge communication. Metaphors stimulate knowledge exchange, especially among users with diversified level of knowledge on a given topic. In the case of laymen-professionals communication, metaphors facilitate effective dialogue by offering commonly understood connotations. Symbolic language is also efficient for discussions conducted by specialists representing different professions and knowledge branches.

SOLUTIONS AND RECOMMENDATIONS

The discussion of the role of metaphors in knowledge management shows how symbolic language can be used in various spheres of life. As has been presented here, metaphors can influence knowledge management in both positive and negative ways. Thus, they have to be chosen carefully in order to facilitate knowledge flows. In addition, taking the dynamic character of KM into account, knowledge creators should select the linguistic

tools that will meet the needs and expectations of participants in knowledge communication.

FUTURE RESEARCH DIRECTIONS

It can be predicted that metaphors will be an important tool of knowledge communication in the future. There are several areas that are likely to influence the metaphorical dimension of knowledge management. The first one is neuroscience, with its tools and methods used in social studies and humanities as well as management. For example, the usage of fMRI (functional magnetic resonance imaging) can facilitate understanding about how people perceive metaphors and how they react to them. Another important branch is technology, offering new ways of coding, decoding, storing and disseminating knowledge. For example, the growing role of video games has led to the appearance and popularity of audiovisual metaphors used in designing player characters (Fahlenbrach & Schröter, 2016). Taking into account the growing role of technology in the twenty-first century, together with the increasing place of non-human actors in interactions (Tatnall & Davey, 2015) and the broad application of computer-assisted tools in linguistic analysis, especially in computational linguistics, another topic of interest is the role of computers in interpreting metaphors (Weber Russell, 2016). The next future direction can be the shift from metaphor as a research object to metaphor as a research tool (Cameron, 2014). Thus, novel research methodologies may offer symbolic communication as a way of studying knowledge management.

CONCLUSION

As has been presented here, metaphors are important in different stages of knowledge management, such as creation, encoding, decoding and

dissemination. This discussion mainly centered on the positive sides of symbolic language in knowledge management. However, it should be remembered that metaphors may also have a negative impact on KM. As with other linguistic choices, the selection of metaphors should mirror the topic to be covered as well as the audience to be addressed.

KEY TERMS AND DEFINITIONS

Figurative Language: Language relying on linguistic tools having non-literal meaning, such as metaphors, metonymies, similes, paradoxes, idioms, puns, etc.

Knowledge Management: Strategies and processes connected with managing knowledge at different stages, such as creation, encoding, decoding, application and sharing.

Metaphor: A non-literal linguistic device relying on known domains to denote unknown or less known domains.

Multimodal Metaphor: A non-literal linguistic device using known domains to denote known or less known domains by applying verbal and pictorial notions.

Pictorial Metaphor: A non-literal linguistic device using known domains to denote known or less known domains by applying pictures, drawings and other forms of pictorial representation; also called a visual metaphor.

Verbal Metaphor: A non-literal linguistic device using known domains to denote known or less known domains by applying words or phrases.

Theory and Practice of Online Knowledge Sharing

Will W. K. Ma

Hong Kong Shue Yan University, Hong Kong

INTRODUCTION

Online knowledge sharing refers to the online communication of knowledge so that knowledge is learned and applied by an individual. Several key aspects of the term can be identified. First, it concerns interactions among individuals who communicate with one another. Second, the use of the term “online” signifies a focus on social interaction through online connections and/or online environments. Third, it involves the exchange of knowledge. Individuals come to understand the knowledge they acquire through the process of online communication and social interaction. More importantly, individuals are able to apply such knowledge in future in a similar or different context. Online communication among individuals thus enables knowledge sharing to take place in an online learning environment such that the learner understands the knowledge acquired and is able to apply it in similar or other contexts. Such a definition distinguishes the *online* context from traditional means of communication and differentiates knowledge sharing from purely emotional support.

BACKGROUND

Knowledge sharing represents a critical step in the knowledge-creation process from a variety of knowledge perspectives. Individuals create knowledge and become knowledgeable or de-

velop expertise. The key to learning is to locate knowledgeable others and to learn from them. However, some knowledge cannot be explicitly described and transferred without a certain kind of interaction between experts and learners. In addition, knowledge may not exist in knowledgeable others or experts, but may be sticky knowledge embedded in communities of practice. Knowledge can be shared only through social interaction among individuals who truly understand the practice within a specific context. Furthermore, the social dimension of knowledge has evolved as an integral part of the process of knowledge creation and knowledge acquisition. Various knowledge perspectives emphasize that knowledge is imparted through continuous transactions between individuals, with social interaction at the forefront of such transactions. For example, Schraw (2006, p. 246) argued that learners actively construct meaning rather than simply assimilating it in a passive manner. The social dimension of learning therefore plays a central role in the construction of knowledge. Schraw suggested that most contemporary educators support such a constructivist view in one way or another. Prawat (1996) suggested that individual-social interaction underlies the knowledge-construction process and rejects the notion that the locus of knowledge is in the individual (p.217). Rather, knowledge is the product of a perfect inferential system between the individual and the social environment. The post-positivist perspective on knowledge states that knowledge sharing is a process of consensual

understanding situated in everyday experience, and holds that knowledge is negotiated among those who encounter and use it.

THE CURRENT STATUS OF THE KNOWLEDGE LITERATURE

Nature of Individual Knowledge Sharing and Learning

A popular socio-cultural theory of learning is that of Lev Semyonovich Vygotsky, who explained the mechanism by which knowledge is acquired and represented through knowledge sharing and social interaction (Vygotsky, 1978). This mechanism comprises two planes: the social/individual plane and the public/private plane. Learning starts on the social plane, with learners acquiring new concepts and strategies through interactions with more knowledgeable others. Individual learners then use and extend the concepts and strategies thus acquired to other contexts, and meanings and interpretations are initiated through social interactions (social to individual). Learning then emerges in the public domain, with the knowledge being used by more knowledgeable others and made available to learners. Through interactions within the public domain, individual learners understand, adjust, and implement the knowledge they have learned in the private domain (public to private). Harre (1984) and Wertsch and Bivens (1992) concluded that the success of learning is based on the assumptions that knowledgeable members of a culture will assist others to learn and that learners will actively engage in learning activities to facilitate higher mental functions. Social interactions are initiated among individual learners and naturally result in knowledge sharing.

Organizational Learning and Knowledge Sharing

Ikujiro Nonaka put forward a dynamic theory of organizational knowledge creation that posits social interaction among individuals as the only

means by which tacit-to-tacit and tacit-to-explicit knowledge sharing can take place. At the fundamental level, knowledge is created by individuals (Nonaka, 1994, p. 17). From an organizational point of view, organizations cannot create knowledge without individuals. Organizations provide a context designed to encourage individuals to create knowledge. Through social interaction in informal communities, organizations amplify the knowledge created by individuals, transform such knowledge, and legitimize it through formal notions of a hierarchical structure. Specifically, Nonaka suggested that knowledge appears in two forms: tacit and explicit. Based on these two forms of knowledge, knowledge is created through four modes of knowledge conversion: from tacit to tacit (socialization), explicit to explicit (combination), tacit to explicit (externalization), and explicit to tacit (internalization). Social interaction appears to be the key conversion process by which tacit and explicit knowledge is created. For example, an individual can acquire tacit knowledge through their interactions with individuals. By way of observation, imitation and practice, individuals gain shared experience and share one another's thinking processes. The key to gaining tacit knowledge is shared experience through a process known as socialization. Another means of extracting tacit knowledge from explicit knowledge involves the use of social processes that combine explicit knowledge held by individuals (p.19). Individuals exchange and combine their existing explicit knowledge through meetings and telephone conversations to re-configure, re-categorize, or re-contextualize such knowledge, thus leading to the formation of new knowledge. The theory of knowledge creation thus underlines the importance of knowledge sharing and the key role it plays in creating new knowledge.

Community of Practice and Knowledge Sharing

Etienne Wenger (1998) developed the theory of communities of practices to explain knowledge embedded in social practices. According to this

communities of practice theory, engagement in social practice is the fundamental process by which humans learn. This concept suggests that learning is a process of social participation, a notion further supported by the fact that learner participation is associated with positive effects on learning, satisfaction and retention. Brown and Duguid (2001) argued that too much attention is often paid to the idea of community and too little to the implications of practice (p.198). They suggested that work practice is critical to understanding the acquisition of knowledge at work. Although it is not greatly connected to the community or to the structure of a formal or informal community, knowledge should be viewed through the lens of practice and the perspective of participation. Knowledge developed through participation will be extended to the social sphere if work practices are social. Knowledge is thus viewed less as something mandated by structure or dictated by culture and more as something that participation helps to create (p.202). In the study of the largest online professional community of practice of teachers in Taiwan, Tseng and Kuo (2014) found that closer connections among online community members can lead to greater recognition of and altruism towards others. The development of social relationships among online members helps them obtain potential resources and reliable support through their social network. Online membership fosters a prosocial attitude that increases their willingness to share useful resources and solve other members' problems both emotionally and instrumentally. Knowledge sharing behaviors, in terms of knowledge giving and knowledge receiving, predicted prosocial commitment and performance expectation. Jahnke (2010) explored the dynamics of social roles in a computer-supported social group structure, in particular, called Socio-Technical Community. The results suggested that a group evolves from an informal trust-based community with few formal roles to a formal Socio-Technical Community structure where the social mechanisms,

not the software architecture, support knowledge management process.

Extrinsic and Intrinsic Motivation for Knowledge Sharing

The willingness to share knowledge is regarded as a prosocial form of behavior, both among individuals in interpersonal relationships and among employees engaging in organizational behavior. While this type of prosocial behavior is practiced on a voluntary basis rather than being forced, the key challenge in knowledge sharing is how to motivate people to share knowledge: why should I share my knowledge with you? Prior studies utilize a number of theories to explain the willingness to share knowledge online, for example, community of practice (e.g., Tseng & Kuo, 2014); uses and gratifications model (e.g., Lee & Jang, 2010); theory of reasoned action (e.g., Arpaci & Baloglu, 2016); theory of belonging (e.g., Ma & Yuen, 2010); intrinsic motivation of altruism (e.g., Diep et al., 2016; Ma & Chan, 2014); self-determination theory (e.g., Pe-Than et al., 2014); sense of community (e.g., Yilmaz, 2016), etc. They examine how both extrinsic and intrinsic motivations affect the intention to share online knowledge and/or actual knowledge-sharing behavior. To cite some of the findings, for example, Diep, Cocquyt, Zhu, and Vanwing (2016) examined altruism and perceived learning benefits as a measure of performance expectancy where social capital with regard to adult learners' online participation. Sense of belonging and norms of reciprocity are found to significantly related to online participation. Similarly, Ma and Chan (2014) draws on the theory of belonging and the intrinsic motivation of altruism to explore the factors contributing to social media knowledge sharing behavior. They found that perceived online attachment motivation and perceived online relationship commitment, and altruism are significantly related to social media knowledge sharing. Furthermore, Yoo and Gretzel (2011) examined the effect of personality

traits on content creation in comparison to only information consumption. Results showed that personality has been found to be a particularly influential trait significantly related to perceived barriers to content creation, motivations to engage in content creation and specific creation behaviors. Another study by Yilmaz (2016) explored and found that academic self-efficacy and sense of community are related to knowledge sharing behavior. In particular, connectedness to the community, learning perception in the community, the self-efficacy of the students on the cognitive applications in the courses and their social status in the community are related to knowledge sharing behavior. In the study of perceived enjoyment for information sharing, Pe-Than, Goh, and Lee (2014) found that perceived needs for autonomy, competence, and relatedness are related to perceived enjoyment. In another study among information technology majoring undergraduates in Turkey, Arpaci and Baloglu (2016) found that cultural collectivism has a positive and significant impact on attitudes toward and subjective norms with regard to knowledge sharing.

An Interpersonal Perspective for Knowledge Sharing

A review of prior studies identifies an important motivation that triggers frequent social interactions, which form the basis of knowledge sharing. Baumeister and Leary (1995) suggested that the need to belong is a fundamental human motivation for frequent and regular social interaction. They defined the need to belong as “a need to form and maintain at least a minimum quantity of interpersonal relationships, [which] is innately prepared (and hence nearly universal) among human beings” (p.499). According to this theory, people are naturally driven toward establishing and sustaining belongingness. Thus, the theory of the need to belong may explain the motivation for social interaction in knowledge sharing through the mechanisms of affiliation motivation (to form

social bonds) and relationship commitment (to maintain those bonds). To satisfy this desire, individuals will try their best to form and maintain relationships through frequent social contact and interaction with others. This provides a basis for explaining the motivation for knowledge sharing. The need to belong stimulates goal-directed activities designed to satisfy it. Motivated by the social goal of satisfying the need to belong, people tend to seek out interpersonal contacts and cultivate possible relationships, and continue doing so until they have reached a minimum level of social contact and relatedness. A recent empirical study found that online knowledge sharing has significant direct relationships with online perceived attachment motivation (the motivation to form a relationship) and online perceived relationship commitment (the motivation to maintain a relationship). Following this line of thought, Ma and Yuen (2010) explored and found significant relationship between interpersonal relationship motivations and online knowledge sharing.

RESEARCH ON ONLINE KNOWLEDGE SHARING PRACTICES

It is commonly argued that the use of information technology improves knowledge sharing through learner participation and interaction in both traditional and online learning. A review of recent empirical studies shows there are several streams of research into online learning that deal with knowledge sharing. The first stream considers online learning provided through a shared platform on which peer learners interact, often in the form of discussion forums, and in which knowledge sharing occurs through the continuous interaction of peer learners engaging in asynchronous written communication (e.g., Lee & Jang, 2010). The second stream examines online learning in shared workplaces that allow peer learners to interact to complete a common task, in which knowledge sharing occurs through continuous interaction

among peer learners who learn by doing (e.g., Cevik, 2015). Another stream holds that online learning provides a transparent demonstration of individual outcomes, and that knowledge sharing occurs through continuous exposure to best practices and learning by observation among peer learners (e.g., Feng & Ye, 2016). A final strand of the literature highlights that online learning provides a centralized meeting place for community building and that knowledge sharing occurs naturally in the presence of human resources and expertise (e.g., Jahnke, 2010).

Many empirical studies of online knowledge sharing measure such sharing in terms of social interaction, participation and engagement, and its relationship to learning. For example, online discussions have been examined by assessing messages posted by learners (e.g., Mazzolini & Madison, 2007); collaborative learning environments have been investigated by assessing interactional activity, participation patterns, and their effects on performance (e.g., Lin & Lai, 2013); and collaboration environments supported by different levels of technology have been assessed by investigating the extent to which learners share knowledge and the resulting effect on individual outcomes (e.g., Eid & Al-Jabri, 2016). Knowledge-building communities have been studied by investigating the sharing of learners' knowledge with other members of the community (Pi, Chou, & Liao, 2013). All of the empirical evidence in these studies indicates that fully utilizing an online learning environment can improve online knowledge sharing.

The examples given below illustrate the best practices using technology to support knowledge sharing in a learning environment.

Asynchronous Virtual Classrooms

Hiltz and Wellman (1997) established one of the first asynchronous virtual classrooms (the NJIT Virtual Classroom) to empirically test knowledge sharing through virtual community building and asynchronous communication. With the help of

the virtual classroom setting, such students can interact online with their instructors and other peer learners at any time and in any place (p.49). This virtual classroom project generated a number of subsequent studies. One such study (Wellman et al., 1996) found that the majority (71%) of students stated they had better access to their professors, and 73% found the virtual classroom "more convenient" overall. Collaborative learning took place online and learning communities were found to exist.

Knowledge Forums

Marlene Scardamalia and Carl Bereiter developed the CSILE (Computer Supported International Learning Environments) system at the Ontario Institute for Studies in Education (Singh & Means, August, 1995). Established in 1986, it is considered the first networked system designed for collaborative learning and has been used as a research program within Toronto schools for a number of years. The CSILE system functions as collaborative learning environment that helps form a learning community using the same database capable of displaying both text and graphics. The dialogue that ensues eventually leads to the accumulation of knowledge. In 1995, Knowledge Forum was developed under the World Wide Web environment to replace CSILE and facilitate its ongoing use to help and support knowledge-building communities. In a recent study, Lee and Jang (2010) explored the motivations to knowledge sharing in online knowledge forums. They found that stronger affiliative tendency, higher self-esteem, or stronger public individuation are more likely to contribute to the open information repository. On the other hand, they also found that these psychological traits significantly enhance individual's intention to share knowledge on a public web site only when other users' presence is rendered salient and individual contributions are visibly acknowledged.

Social Networking Sites

The recent development of social networking sites brought new opportunities for knowledge sharing and learning. Social networking is a basic human need to associate, communicate, and collaborate with one another, and to share ideas, feelings, observations, and thoughts with others. With the help of social networking platforms developed in recent years, social networks form online and allow us to interact, share, educate, and connect to extend our physical interpersonal relationships to build trust and to form relationships in the virtual world (Safko, 2013, pp. 46-47). Recent studies examined the process of knowledge sharing in social networking and explained the process with social networking theory and analysis. For example, Eid and Al-Jabri (2016) examined the various categories of social networking sites use including chatting and online discussion, creating knowledge and information content, file sharing, and enjoyment and entertainment by undergraduate students. They found that there are significant positive relationships between both chatting and online discussion and file sharing and knowledge sharing, and entertainment and enjoyment with student learning. Lin and Lai (2013) utilized social network analysis to find that social network awareness increases participant rate and opportunities of knowledge sharing and helps promote learning achievement. In particular, students with higher centrality (regardless of degree and closeness) are more likely to take advantage of the social network position to ask for help; easily become target helpers that peers seek to; utilize the social network more frequently; and have better learning achievement. Another study (Pi et al., 2013) found that reputation affects knowledge sharing attitude; sense of self-worth affects attitude through subjective norm; social networking sharing culture (fairness, identification, and openness) is related to knowledge sharing intention through attitude and subjective norm.

MEASUREMENT OF ONLINE KNOWLEDGE SHARING

Ko et al. (2005) argued that although many scholars have conceptualized knowledge sharing or knowledge transfer, relatively few have attempted to measure it directly (p.68). Based on the study of Argote and Ingram (2000), Ko et al. (2005) define knowledge sharing as “the communication of knowledge from a source so that it is learned and applied by a recipient” (p.60). They developed and empirically tested a six-item instrument in which three items address the learning component and the other three items assess the application component.

Based on the investigations of Zander and Kogurt (1995) and Ko et al. (2005), Brown et al. (2006) examined the perceived value of the knowledge-sharing process to determine whether and how much knowledge sharing occurred. They argued that perceptions are more useful in measuring across-domain knowledge sharing, whereas specific tests of knowledge content are narrow in their application because of their context-specific nature (p.2). Based on person-to-person knowledge sharing, this study put forward and empirically tested a ten-item scale to measure the value of knowledge sharing composed of four components: efficiency, quality, learning, and understanding. The study generated four key findings. First, a knowledge-sharing process helps employees save time in performing their jobs; second, knowledge sharing improves the quality of work performed; third, for knowledge sharing to be truly valuable, it must enhance learning; fourth, for knowledge sharing to be truly beneficial, it must facilitate sharing of the deep structures necessary to apply that knowledge (i.e., understanding). More recently, Ma and Yuen (2011a, 2011b) developed and validated an online knowledge-sharing scale, using two samples from two different online learning environments. This is a five-item instrument in which two items measure the learning component and three items assess the application component.

CONCLUSION

Although the issue of what factors motivate knowledge sharing remains an open question, Facebook usage statistics clearly show that sharing is a fundamentally natural process. For instance, Facebook statistics shows that the site has 1.13 billion daily active users on average; photo uploads total 300 million per day; 4.5 billion likes generated daily; 4.75 billion pieces of content shared daily (Zephoria.com, 2016). The popularity of this social media site demonstrates that people frequently engage in social interaction and sharing. What we are less certain of and which therefore requires further exploration, is what inhibits us from sharing, especially in an online knowledge-sharing context. For example, although it is known that learning conceptions and learners' self-concepts affect learners' approaches to learning and learning outcomes (e.g., Burnett, Pillay, & Dart, 2003), do different learning conceptions affect interaction and knowledge sharing among peer learners? Studies of interpersonal relationships have shown that differences between individuals affect how people approach others. Nevertheless, although technology enhances our ability to communicate, does it enhance online knowledge sharing or inhibit it instead? For example, Waycott, Sheard, Thompson, and Clerehan (2013) identified a number of concerns while sharing students' work including students' fear of copying, poor online conduct, and the risk that students may feel exposed when publishing their work online. Thus, sharing process creates tension between the collaborative and participatory nature of the social networking, and the competitive and individual nature of the undergraduate assessment in formal education.

FUTURE RESEARCH DIRECTIONS

Do we understand the above concerns well enough? This would also be an important topic for further exploration.

KEY TERMS AND DEFINITIONS

Asynchronous Communication: A mediated form of communication in which the sender and the receiver are not concurrently engaged in communication.

Computer Supported Collaborative Learning: A kind of learning through sharing and construction of knowledge that takes place via social interaction using a computer or through the Internet.

Explicit Knowledge: The kind of knowledge which has been or can be articulated, codified, and stored in certain media that can be readily transmitted to others.

Extrinsic Motivation: The kind of motivation which comes from outside of the individual.

Intrinsic Motivation: The kind of motivation which is driven by an interest or enjoyment in the task itself, and exists within the individual rather than relying on any external pressure.

Online Knowledge Sharing: online communication of knowledge so that knowledge is learned and applied by an individual (Ma & Yuen, 2011b).

Social Networking Site: A social networking service (also social networking site, SNS or social media) is an online platform that is used by people to build social networks or social relations with other people who share similar personal or career interests, activities, backgrounds or real-life connections.

Tacit Knowledge: The kind of knowledge which is difficult to transfer to another person by means of writing it down or verbalizing it.

Virtual Communities: A social network of individuals who interact through specific media, potentially across geographical and political boundaries in order to pursue mutual interests or goal.

Visualization as a Knowledge Transfer

Anna Ursyn

University of Northern Colorado, USA

INTRODUCTION

There is growing significance of both visual literacy and knowledge of visualization, where visualization means communication of data, information, and knowledge with graphical representations. Knowledge visualization has become a cross-disciplinary, interactive culture and the element of the utmost importance in science education because of a need to convey the information to students about advances in technologies. Possibly, visualization is the best way of learning, teaching, or sharing the data, information, and knowledge because it amplifies cognition, outperforms text-based sources, and increases our ability to think and communicate. For all these reasons visualization ability should be introduced and trained since kindergarten.

This text presents selected concepts, methods, and tools related to visualization of data, information, and knowledge. It presents some approaches to the concept of visualization and the ways it mediates between the user and the physical world. It overviews visualization tools and applications, and discusses the importance of visualization methods for the current educational strategies.

BACKGROUND

Information is usually presented in numerical, graphic, or diagrammatic form; it may be shown as a sketch, drawing, diagram, plan, outline, image, geometric relationship, map, music and dance notation, object, interactive installation, or a story. Diagrams visualize information in a pictorial yet abstract (rather than illustrative) way: as plots, line-graphs and charts, or the engineers or archi-

itects' blueprints. Complicated presentations of data organization and interpretation, for example governmental statistics are easier to comprehend in a graphic than in a numerical form, when they serve as explanatory tools for the data sets. Thus, visualizations change numerical data into graphs, clouds (Chen, 2010), tree visualizations (Shneiderman, 2014; Lima, 2014), network data, time-based, interactive, metaphorical visualization designs, and other formats.

Visualization means the communication of information with graphical representations. At the present time, visualization means using the computer, which transforms data into information, and then visualization converts information into picture forms. Graphic images and symbols convey and express the meaning of abstract data, which lets us comprehend data and make discoveries, decisions, or explanations about patterns or individual items (Shneiderman, 1996). Thus communication through visualization is at the same time pictorial and linguistic. It is socially and culturally conditioned, based on familiar linguistic patterns, as in a 'pie chart' metaphor for market shares, or a 'starry night' metaphor showing data in 3D (Bertschi & Bubenhofer, 2005).

Cognitive way of learning and teaching may involve cooperation with specialists in several disciplines. Computer scientists and artists apply visual way of presentation while working, for example with mathematicians, anthropologists, designers, and architects to conduct computer analysis of facades and architectural details. Professionals performing scientific presentations and researchers in fields of natural sciences, medicine, pharmacology, biology, geology, or chemistry examine and visualize symmetry and patterns in natural and human-made structures. Many artists

DOI: 10.4018/978-1-5225-2255-3.ch443

have created masterpieces this way. Visualization serves as an efficient tool that assists practitioners creating communication media-art, installations, animated video or film, architectural projects, designing newspapers and magazines, or working on website design. Users apply visualizations to understand how data analyses and queries relate to each other. From simple charts and data graphics to 3D multi-user virtual reality environments happening in real time with human interaction possible, visualizations let us fly around the organized data, comprehend, and make decisions (Chen, 2010, 2011). Structural modeling of the relationships may involve the use of graphs, trees, or cones; detecting proximity and connectivity; clustering and classification using word search; multi-dimensional-scaling; network analysis; glyphs (single graphical units portraying many variables by adapting their properties) on charts and graphs; virtual structures; applying complex network theory, and network representations (Chen, 2010).

Visualization enhances communication through information display with the use of letters, numerals, art, graphic design, visual storytelling, signs, symbols, and application software. Drawing basic shapes like squares, triangles, and circles connected by lines and arrows, and then inserting simple drawings inside of these shapes creates visualization of our concepts. Graphs, diagrams, or animations can visualize messages as well. Examples of the non-visual creations are multi-modal interactive data presentations, sonifications, and haptic/touch interfaces, for example pressure sensitive interfaces. Visualization has also been considered a semiotic process because of the use of signs to present ideas.

There is a wide range of visualization techniques, still growing along with the developments in computing and information technology. Visualizations help explore and understand complex data, communicate, and navigate on the web. Visualization industry uses software and programming solutions, along with the great amount of the cultural, historical, and architectural research.

Examples may include a study on the Napoleon's campaign (Tufte, 1983,1992) or a Periodic Table of Visualization Methods (Lengler, & Eppler, 2008). Time-based, 3D, and augmented reality applications serve for the military, intelligence, aviation and air traffic control, medical education, and other purposes.

Metaphorical Language of Visualization

Visual metaphors make a basic structure in visualization because they describe relations among data, organize information in a meaningful way, and combine creative imagery with the analytic rationality of conceptual diagrams. A metaphor indicates one thing as representing another, difficult one, thus making mental models and comparisons. Instead of developing a nomenclature specific for computing, we apply metaphors – names of familiar items and actions for organizing computing-related items and activities: we open a new window or a file with a mouse, put them in a folder, we cut, copy, and paste, place icons on a desktop, use tools and search engines, canvas, mailbox, documents, in-and-out boxes, and a web portal. The desktop metaphor is now fading because cell phones and tablets are replacing PCs as the main gateway to the Internet. We may use graphics or show virtual environments, often shaped by artist's fantasy; the success and quality of any visualization depend on imagination, the retrieval of necessary data, the choice of a metaphor, and the delivery method: whether to apply animation, interconnection, or interaction. Visual metaphors can either be natural objects or phenomena (e. g., mountains, tornados) or artificial, man-made objects (e. g., a bridge, a temple), activities (climbing), or concepts (war, family). Metaphors organize, structure information, and convey an insight through characteristics or associations. Metaphors may convey topics such as theological events or encyclopedias' tables of contents, and serve as classification systems (Lima, 2011).

Communication involves language, and pictures need a caption. Because language is metaphorical, our thoughts are mostly metaphorical. To communicate knowledge in a dynamic, interactive way, often in real-time, visualizations provide two-dimensional and tree-dimensional metaphors, familiar and understandable in social and cultural terms. Metaphors traditionally used in visualizations show programs or data as natural objects, such as a solar system, or man-made objects, for example a city, architecture, house, parking lot, metro, library, street, but also they map the data to facial expressions, video games, or nested boxes. A city metaphor may represent a software package; navigating through software may enhance program understanding or lessen costs and effort of software production and maintenance.

VISUALIZATION DOMAINS

The most important domains in visualization are: data visualization, information visualization (when somebody presents what has been done with the data), and knowledge visualization. New approaches to visual way of processing change with the growth of communication media, social networking, cloud computing, and GPS.

Data Visualization

Data visualization presents the sets of data in a visual form, and thus enables us to go from the abstract numbers in a computer program (ones and zeros) to visual interpretation of data. Sabol (in Bertschi, Bresciani, Crawford, Goebel, Kienreich, Lindner, Sabol, & Moere, 2011, p. 333) describes data as “sequences of numbers or characters representing qualitative or quantitative attributes of specific variables. Many types of physical or numerical data may include 1D linear, 2D (e.g., a map), 3D (e.g., molecule or architectural models), multidimensional (scattergrams, clusters), and other types. Data visualization applies tools that have been listed as techniques for spatial

and geospatial data, imaging multivariate data, visualization of trees, graphs, and networks, text representations, and interaction techniques (Ward, Grinstein, & Keim, 2010).

Information Visualization

Information Visualization means the use of computer-supported, “interactive visual representations of abstract data to amplify cognition” (Bederson & Shneiderman, 2003; Card, Mackinlay, & Shneiderman, 1999). Ben Shneiderman included theoretical approaches and discussion about visualization as a scientific discipline. He proposed the Visual Information Seeking Mantra and also the task-by-data-type taxonomy. Mantra serves as a methodological guidance to practitioners who design novel systems. According to the classic Shneiderman’s information visualization seeking mantra (1996), visualization should support seven high level tasks: overview, zoom, filter, detail-on-demand, relate, history, and extract. Craft and Cairns (2005, 2008) elaborated this notion in prescriptive way. It has been also described as representation plus interaction, which often derives new insights. Creating visualizations includes transforming raw data (that may be abstract, semantic, or verbal information in hypertext, www, or other text documents) into structured data as data tables, converting data for calculations of their attributes, and visual mapping of important structures into the abstract visual structures. Users transform these structures on a screen changing their shape, color, size, or location. Designing information visualization has been described by Shneiderman as importing and cleaning data, combining visual representations with textual labels, finding related information, viewing large volumes of data, integrating data mining, integrating with analytical reasoning techniques, collaborating with others, achieving universal usability, and evaluation (Fowler, 2012).

Information visualization may have a great variety of applications. It may serve scientific theories and fields including applications of graph

theory, geometric modeling and imaging, visual analytics, virtual environments, geo-analytics, biomedical informatics and visualization, web visualization, cultural heritage knowledge visualization, aesthetics, visualization in software engineering, architecture, visualization in built and rural environments, and many other fields. It serves for conveying information in online journalism, business management, technical writing, social networks, and education. Software architecture can be understood easier when a visual query helps us to find patterns of highly connected components in a node-link diagram. Visualization techniques are used in conjunction with medical treatment including cancer treatment.

Network and web-search result visualization became the main carrier of information. Visual search engines use information visualization, data mining, and semantic web. Navigation systems make a website opening fast, visually appealing, containing all information needed, and easy to find. Web architectures use search engines, manage large databases, and create web interfaces based on the concept of the semantic web. Surfing the web involves visualizing and manipulating data in multiple dimensions, using Java, 2D and 3D interaction metaphors, and data mining.

Knowledge Visualization

Knowledge Visualization uses visual representation to transfer insights to create, integrate, and apply knowledge, rather than data, between individuals; it focuses on the recipients, other types of knowledge, and on the process of communicating different visual formats (Burkhard, Meier, Smis, Allemang, & Honish, 2005). It has been widely accepted that knowledge visualization provides new knowledge in the process of communication between at least two people (Card, Mackinlay, & Shneiderman, 1999). Techniques are aimed at explanation and presentation of knowledge, so they enhance cognitive processes of users and reduce cognitive load for working memory.

Knowledge visualization can be created without the use of a computer. A cave drawing, a map, or a mind map drawn with a pen on paper may serve as examples of knowledge visualization generated without a computer. Knowledge visualization has been present in different disciplines and in various modes since early days of civilization. Tables of the past acted as visualization modalities (Marchese, 2011). Many kinds of tables preserved since ancient times; the Near East Akkadian clay tablets, Sumerian accounting tables, Aztec calendars, or the Egyptian stele Rosetta Stone, as well as the medieval chronicles, canon tables, and calendars are representations of early genres in information visualization. Analysis of these tables demonstrates the constant need to visualize abstract data, information, and knowledge.

Knowledge visualization specialists use computer-based (and also non-computer-based) graphic representations, such as information graphics (infographics), objects, sketches, conceptual diagrams, images, concept maps, animations, interactive visualizations, storyboards, and visual metaphors to produce solutions concerning readability, simplification, and effectiveness of presentation for a wide spectrum of users. Designers co-work with communication science specialists for social network users (such as cell phone users, e-mail archives, criminal networks, or underage audience sensitive messages). Knowledge visualization could contribute design- and user-specific representations, e.g., a map, metro, aquarium, solar system, or flower metaphor for users with limited visual literacy (Kienreich, in Bertschi et al., 2011).

Scientific Visualization

Scientific Visualization was established in 1985 at the National Science Foundation panel. McCormick, DeFanti, and Brown (1987) defined scientific visualization as a field in computer science that encompasses user interface, data representation, processing algorithms, visual

representations, and other sensory presentation such as sound or touch (McCormick et al., 1987). Abstract or model-based scientific visualizations present real objects in a digital way. Scientific visualization (mapping from the computed to perceptual representations) focuses on maximizing human understanding, usability, effectiveness, and efficiency. Physically based data are defined, selected, transformed, and represented directly from the data according to space coordinates, such as geographic data or computer tomography data of a body for medical use. Visualization as storytelling comprises narratives, interactive graphics, explanatory and animated graphics, and multimedia. Analysts, decision makers, engineers, or emergency-response teams depend on the ability to analyze information contained in the data; they also search how users navigate the database.

Concept Mapping

Concept Mapping represents the structure of information visually and builds knowledge models useful for strategic planning, product development, market analysis, decision-making, and measurement development. Concept maps support the learning, construct knowledge, reduce cognitive load, and improve recall of information. Knowledge maps visualize knowledge by showing changes and interrelationships; they help us design strategies and build assessment. Network and web-search result visualization became the important carrier of information. Visual search engines use information visualization, data mining, and semantic web.

Visual Analytics

Visual Analytics provides automated analysis of large amounts of dynamic information and the closed loop approach with visualization and interaction utilizing multi-touch surfaces; combines computational and visual methods using visualization, data mining, and statistics; uses abstract

visual metaphors, mathematical deduction, and human intuitive interaction. Visual analytics serves for studying the entire genome of an organism at many abstraction levels: cells, organisms, and ecosystems, in formats and scales such as molecules, gene networks, and signaling networks. It also serves medicine, environmental research, and national security. Tag cloud visualization is a text-based visual representation of a set of tags.

Information Aesthetics

Information Aesthetics forms a cross-disciplinary link between information visualization and visualization art. Information visualization is often evaluated on representing data in pleasurable and intelligible way. Visualization not only makes the unseen visible, it is building a meaningful net of associations and connotations. The developments in computing technology may cause that aesthetics of knowledge visualization may be measured as the balance between art literacy and technological literacy: visual competence in the art, design, and technological solutions in visualization. Aesthetic values are considered important in mathematics, science, and computing, including the aesthetic computing and aesthetic issues related to digital environment.

In the field of product design, product visualization supports market research and advertising; a grasp of visualization technologies is a requisite for designing effective visual marketing. Critics and audience expect the inclusion of functionality, effectiveness, and efficiency into evaluation of the product. This needs consideration whether an object's design fulfills the functional, ergonomic, aesthetic, material- and space-related demands, along with the product's comfort, simplicity, elaboration, message, or easiness of use. Visual literacy supports the quality design and product aesthetics. For Edward Tufte (1983/2001, 1992/2005), good design has two key elements found in simplicity of design and complexity of data. Frøkjær, Hertzum, and Hornbæk (2000) connected usability with ef-

fectiveness – the accuracy and completeness with which users achieve certain goals; efficiency – the relation between effectiveness and the resources expanded in achieving them; and satisfaction – the user’s comfort with and positive attitudes towards the use of the system.

Product visualization can extract its high-quality features and present them as quite distinct images in a way that everybody can apprehend the product’s values and buy the marketed article. The objectives of aesthetic studies also move toward the effectiveness, efficiency, and easiness to understand (a low cognitive cost) of visual presentation, not exclusively to the beauty of an image. Informative art works are not only aesthetical objects but also contain information. Researchers usually associate aesthetics with readability, and readability with understanding.

Tools for visualization may serve as in terms of cognitive instruments such as utilization of a metaphor, simulations, or the use of layers, details, and complexity in a website. Tools and instruments for visualization are derived from many domains; they may include scanners, microscopes, and cameras, along with many kinds of applications for recording and measuring in real time, micro agents, or bots. In terms of computing one may apply computer graphics tools such as Photoshop, and also the computer networking related concepts such as cloud computing. Clustering technique (clusters are subsets of observations) is used in data mining for statistical analysis, pattern recognition, and bioinformatics.

Infographics refers to tools and techniques involved in graphical representation of data, information, and knowledge, mostly in journalism, art, and storytelling. Models of information management address the data presentation, mapping, and issues related to the temporal dimension. A model may mean a scaled copy of some object (often using interactive modeling systems), or a mathematical model describing physical laws and the behavior of physical objects.

CURRENT APPROACHES AND APPLICATIONS

Visualization techniques may support the present-day trends in science education strategies. They allow presenting the mathematical theories and their proofs, along with the computing science related theories as two-dimensional and three-dimensional constructs. For educational the purpose, placing a great emphasis on developing visual literacy in students may be beneficial in fulfilling this task. For example, students may create mathematically programmed sculptures, or the fractal based art works, sceneries, and backdrops. Some versed in programming would be coding music- and dance-related shapes and form, thus creating music visualization.

Current means of delivering knowledge include for example, the use of 3D printing (Mercuri & Meredith, 2014) or augmented reality (Bredl, Groß, Hünninger, & Fleischer, 2012). 3D printing technology and open source printers just arrived to the school environment (Irwin, Opplinger, Pearce, & Anzalone, 2015); Schelly, Anzalone, Wijnen & Pearce, 2015). In the 3D printing technology based on the rapid prototyping process, additive processes are used, with successive layers of thermoplastic material laid down according to a computer program (Grujović, Radović, Kanjevac, Borota, Grujović, & Divac, 2011; Ravikumar, Khan, Mohanty, Sageer, & Aigali, 2015). Thus for example, the Voronoi tower can be created. Two- and three-dimensional Voronoi diagrams (Voronoi tessellations) are now commonly applied in architectural concepts, and other science and technology fields. Using the 3D printing technology and dinosaur fossils from the American Museum of Natural History paleontology collections, a group of high school students learned to think like paleontologists while producing models of dinosaurs as part of the innovative program “Capturing Dinosaurs: Reconstructing Extinct Species Through Digital Fabrication” (American Museum, 2013).

In educational terms, scientific visualization may present the art-science cooperative learning projects in order to make knowledge comprehensible both to the students and to a wide audience. Artists used to transform patterns and repetitions to apply the unity or symmetry in their compositions (for example, by examining a Fibonacci sequence, prime numbers and magic squares, a golden section, or tessellation techniques). Mathematicians, computing scientists, and artists used to apply visual metaphors as a cognitive tool to visualize the world's structure and our knowledge. For example, hierarchical structures are predominantly analyzed with the use of a tree metaphor. Manuel Lima called the tree figure the most ubiquitous and long-lasting visual metaphor, "through which we can observe the evolution of human consciousness, ideology, culture, and society" (Lima, 2014, p. 42). Figure 1 presents a work of a student Hunter Shioshita of the University of Northern Colorado entitled "The History of Rock and Roll" designed in a tree format.

According to Lima, visualizations fall into all three categories of science, design, and art; they are used as a tool for understanding data – i.e.

discovering patterns, connections, and structure. As a scientific tool, information visualization serves for discovery of new knowledge; as a design tool it facilitates the perception of patterns and evokes emotions in the viewers; as art it is a technique to produce something non-utilitarian and aesthetically interesting (Lima, 2011, p. 12). In the Manuel Lima's book (2011), Lev Manovich indicates the important features that make information visualization unique: projects are visually dense, with more data; they show relations between data; in aesthetical terms, they show complexity (chaos theory, emergent complexity theory) rather than reduction (breaking down into the simplest elements).

SOLUTIONS AND RECOMMENDATIONS

Combining visualization techniques with the recent advances in the selected fields of science would comply with the actual trends in education described as the STEM (science, technology, engineering, and mathematics) and the STEAM

Figure 1. Hunter Shioshita, *The History of Rock and Roll* (© 2005, H. Shioshita. Used with permission)

(science, technology, engineering, arts, and mathematics) programs in education. Integration of science, technology, and art offers a response to the actual trends in education described as the STEAM (science, technology, engineering, art, and mathematics). Many educators have been working toward transforming STEM into STEAM as a framework for teaching across the disciplines (STEM to STEAM, 2014; Gonzalez & Kuenzi, 2012; Maeda, 2012). This trend results from the growing technological literacy in small children who can now use software to learn science, mathematics, programming, and storytelling.

The existing and coming tendencies and solutions in educational and instructional environment should include solving problems through knowledge visualization. Learning programming languages should enhance programs for Studio Art. Students should learn, create, and play together globally through educational games, VR, teaching oriented apps, social networking, and meaningful communication, K through PhD (DeVry University, 2014). Technologies, and practices aimed at enhancing visual literacy and thus supporting learning about science may include toys, games, puzzles, apps, models (often involving 3D printing), animations, simulations (automatic pilot, control tower), and augmented reality environments, among other solutions. Perhaps there is a need for focus on games, apps, and ways to interact through social networking that would bring more learning opportunities, actively converting exchange of ideas into somehow curiosity-based learning realm.

In business corporations and commercial companies there is a trend to include the arts in business, and thus support teambuilding, communication, and leadership. It is also a response to the economical and social demands for the arts-based development training, which became used in corporations. Not only we should integrate scientific, technical, and artistic topics, but also construct, envision, and explain through visuals and interactivity (Honey, Pearson, & Schwein-gruber, 2014).

FUTURE RESEARCH DIRECTIONS

Research on neuronal networks in the brain and its organizational principles may shift the focus of visualization trends. For example, John O'Keefe, along with May-Britt Moser and Edvard I. Moser performed a study on grid cells in brain that was awarded the 2014 Nobel Prize in Physiology or Medicine. According to John O'Keefe, grid cells perform as "inner GPS" that helps the brain navigate through the world" (Devlin, 2014). The cells work together to perform cognitive functions; they provide a context-independent metric representation of local environment (Giocomo, Moser, & Moser, 2011). The firing of the grid cells forms a positioning system in the brain, which tells about the animal's speed and running direction at each location in the environment (Moser, Moser, & Roudi, 2014). Computational models of grid cells present how the neurons fire within a tessellating pattern, and how firing properties depend not primary on sensory signals but rather on internal self-organizing principles.

Current perspective on visualization techniques may evolve accordingly to the developments in technologies that provide an extension or augmentation of the sensory apparatus of the student or child (Eisenberg & Eisenberg, 2015). Novel types of scientific instrumentation: for example, telescopes and microscopes are extending the range of vision, and Geiger counters extend sensitivity to phenomena such as radioactive decay. In a way, eyeglasses, hearing aids, or walking sticks and prosthetic devices work that way by improving or repairing our senses. Another venue in sensory augmentation is in the burgeoning area of wearable technology, pervasive/ubiquitous computing, and prosthetics (Eisenberg & Eisenberg, 2015). There seems to be a great potential for visualization of the nanosize objects and events because nano objects are invisible and inaccessible otherwise.

Developments in visualization may go in parallel with those in other scientific areas. For example, the quality of imaging with optical microscopy depends on the right selection of a microscope

according to the imaging depth needed (de Grand & Bonfig, 2015). Super resolved fluorescence microscopy brought optical microscopy into the nano dimension and won the 2014 Nobel Prize (Chang, 2014). The U.S. National Nanotechnology Initiative defines nanotechnology as “the understanding and control of matter at dimensions between approximately 1 and 100 nanometers, where unique phenomena enable novel applications. Encompassing nanoscale science, engineering, and technology, nanotechnology involves imaging, measuring, modeling, and manipulating matter at this length scale” (Nanowerk, 2015).

Materials seen in the nano scale used to display the size-dependent properties resulting from quantum effects. These properties are distinct from those of materials controlled by laws of classical physics; hence their physical, chemical, and biological characteristics may be different at the macroscopic scale (Nanowerk, 2015). For example, visualizing butterfly wing scales look not the same when seen at different magnifications: a wing that is dark blue when looked at without magnification becomes yellow at 220x magnification, purple at 5000x magnification, and green at 20000x magnification (PennState Modules, 2011).

Future applications of visualization techniques may surely include bioimaging and numerous related bio inspired technologies in science, engineering, medicine, pharmacology, and many other disciplines. The discipline of bioimaging explores biological structures and functions to create information visualizations in two, three, or four dimensions. Bioimaging researchers gather and analyze information from sources such as light waves, nuclear magnetic resonance, x-rays, or ultrasounds. Current methods of bioimaging may comprise optical light microscopy, several medical imaging techniques such as magnetic resonance imaging, nuclear magnetic resonance imaging, magnetic resonance tomography, functional magnetic resonance imaging, and many other advanced approaches involving microspec-

troscopy, to investigate structures at the scale of micrometers.

Other fields that involve visualization comprise Raman spectroscopy, photoacoustic imaging techniques, bioimaging with fluorescence, magnetic supernanoparticles, bioimaging with laser near-infrared (NIR) fluorescence, imaging with multifunctional nanostructures, among a number of other technologies. For example, researchers are developing the infrared camouflage tape for military use inspired by the squid skin properties (No author, Squid skin, 2015). Recently, imaging up to 8 mm into a fixed tissue is possible in multiphoton microscopes. These systems do not require slicing and thus damaging tissues, and thus can be used to provide neurobiological and other information about deep, intact structures. Lasers with dual-wavelength ultrafast (femtosecond) pulses provide simultaneous activation of multiple neurons (Arrigoni & Gallaher, 2015).

CONCLUSION

Significant characteristics of current culture of information systems include visualization techniques, interactive visualizations, and the visual content analysis applied to data and knowledge. The use of visualization techniques in various kinds of presentations plays pivotal role in communication media and educational programs. Nature derived metaphors serve as the enrichment of bio-inspired, interdisciplinary models and support data visualization, information and knowledge visualization, data mining, and semantic web. This caused a need for combining metaphorical visualization with artistic principles and working on metaphorical way of learning and teaching using art and graphic metaphors for the information and communication purposes. Visualization that help making a progress in science provide a set of reasons and a logical basis why visualization ability should be taught and trained since early childhood.

KEY TERMS AND DEFINITIONS

Algorithm: A mathematical sequence of instructions telling how to carry on computation to implement it as a program. Algorithm serves for

solving a complex problem by writing a sequence of simpler, unambiguous steps.

Concept Map: A graphical two-dimensional display of knowledge. Concepts, usually presented within boxes or circles, are connected by directed arcs that encode, as linking phrases, the relationships between the pairs of concepts.

Data Visualization: Information abstracted in a schematic form to provide visual insights into sets of data. Data visualization enables us to go from the abstract numbers in a computer program (ones and zeros) to visual interpretation of data. Text visualization means converting textual information into graphic representation, so we can see information without having to read the data, as tables, histograms, pie or bar charts, or Cartesian coordinates.

Infographics: Tools and techniques involved in graphical representation of data, mostly in journalism, art, and storytelling.

Information Visualization: Often characterized as representation plus interaction, means the use of computer-supported, interactive visual representations of abstract data to amplify cognition and derive new insights.

Knowledge Visualization: Uses visual representations to transfer insights and create new knowledge in the process of communicating different visual formats.

Pattern: The regular order existing in nature or in a manmade design. In nature patterns can be seen as symmetries (e.g., snowflakes) and/or structures having fractal dimension such as spirals, meanders, or surface waves. In computer science, design patterns serve in creating computer programs. In the arts, pattern is an artistic or decorative design made of recurring lines or any repeated elements. We can see patterns everywhere in nature, mathematics, art, architecture, and design. Patterns make a basis of ornaments, which are specific for different cultures.

Scientific Visualization: Presents real, abstract, or model-based objects in a digital way directly from the data. Visualization as storytelling comprises narratives, interactive graphics, explanatory and animated graphics, and multimedia.

Mobile Testing System for Developing Language Skills

Svetlana Titova

Far Eastern Federal University, Russia

INTRODUCTION

Recent research demonstrated that language skills can be enhanced through mobile technologies that transformed drastically foreign language learning/teaching experience offering immediate diagnosis of learning problems and design of new assessment models (Cooney & Keogh, 2007); creating mobile networking collaboration (Lan, Sung & Chang, 2007; Pemberton, Winter & Fallahkhair, 2010), enhancing autonomy (Murphy, Bollen & Langdon, 2012); providing instant feedback and a personalized learning experience (Voelkel & Bennett, 2013; Oberg & Daniels, 2013); enabling teachers to create new formats of problem-solving tasks based on augmented reality (Cook, 2010; Driver, 2012).

But in spite of the plethora of research in the area of mobile learning, it challenges instructors to examine how the pedagogical potential provided by mobile technologies relates to their teaching aims, methods, and subject matter because there is not yet consistent MALL methodology. There is a need for a new educational framework for mobile testing apps implementation aimed at developing learner skills rather than just assessing learner knowledge. The hypothesis to guide the framework of this research includes enquiry-based learning pedagogy and educational opportunities provided by ubiquitous devices such as interactivity and immediate feedback. This study supported by both current m-learning theory and enquiry-based approach focuses on working out a methodological framework for mobile testing system implementation into the language classroom.

BACKGROUND

Today teachers who would like to meet the expectations of a new generation of mobile natives need to follow a transformational approach (Puente, 2011) to the development of language skills based on creative use of mobile technologies within the learner-oriented environment. The main prerequisite of this environment functioning is collaborative peer-learning approach. The social framework, learners' expertise, and cultural practices are gaining importance, the role of the devices is becoming less important. Mobility is no longer defined through the devices, but through "the learners' abilities to act flexibly in ever changing and self-constructed learning contexts" (Seipold, 2011, p.32). Seipold argues that only if teachers provide spaces to learners to act according to their interests, agency, and cultural practices, innovative use of the devices can be discovered by learners (2011).

The research framework is also based on Mishra and Koehler's model for implementing new technologies into teaching - Technological Pedagogical Content Knowledge (TPCK) (2006). This approach suggests teachers should be aiming to reach a point where their traditional content and pedagogical knowledge is enhanced by technological knowledge. According to TPCK framework, a new tool complements teachers' knowledge and skills. This theoretical perspective suggests that learning is affected and modified by the tools employed for it and that reciprocally these tools are adjusted in the way they are used for learning. As Stockwell and Hubbard argue: "Let the language

learning task fit the technology and environment, and let the technology and environment fit the task” (2013, p.9). The Substitution Augmentation Modification Redefinition model developed by Puentedura (2011) can be used as a complement to TPACK. According to this model the use of new tech tools in education may lead either to the enhancement of education (augmentation and substitution phases) or to the real transformation (redefinition and modification phases). Redefinition is the highest transformation phase which allows for a completely new format of tasks and activities that were previously impossible. This approach also offers a perspective in which the pedagogical considerations shape the design of mobile learning.

Other important theories that have been influential to work out the framework of this research are enquiry-based learning and behaviorist approach. Many researchers today highlight social aspects of mobile technologies proposing complex structures of m-learning pedagogy built on Vygotsky’s hypothesis about the importance of discussions in an educational context (Sharples, Taylor, & Vavoula, 2007). Enquiry-based learning is a shift away from passive methods to the problem-based methods through which students are expected to construct their own knowledge and understandings by taking part in supported processes of enquiry (Kahn & O’Rourke, 2005).

Danaher, Gururajan, and Hafeez-Baig (2009) propose the m-learning structure based on three principles: engagement, presence, and flexibility. Presence is characterized as an interaction which is sub-divided into three types: cognitive, social and teaching. Kearney, Schuck, Burden and Aubusson (2012) argue that the main constituents of m-learning pedagogy are personalization, authenticity, and collaboration. Mobile technologies enable instructors to create collaboration environment that motivates students to learn for themselves, bringing a research-based approach to the subject. This interactive, “dialogic models of learning are similar to the processes of participation in research” (Sambell, 2010, 56).

Ubiquitous access to information via mobile devices potentially enables a paradigmatic shift in education, it changes the way classes are managed and the instructor’s role (Beatty, 2004). Kahn and O’Rourke (2005) argue that enquiry-based learning encourages students to seek out new evidence for themselves and support peer learning approach. This approach implies a principal change in the paradigm of teaching due to the fact that mobile devices effectively “act as accelerators of the social discourse” (DeGani, Martin, Stead, & Wade, 2010, p.181).

THE PEDAGOGICAL POTENTIAL OF THE MOBILE TESTING SYSTEM PELE TO ENHANCE LANGUAGE LEARNING

The mobile testing system PeLe for handheld devices, developed at Sør-Trøndelag University, enables instructors to deliver a test through any mobile device, assess it and provide timely feedback to both individual students and a group of students immediately after a test. Using Pele students can respond to tests electronically and the teacher can see on the screen what is happening during the test. The technological characteristics and the pedagogical potential of PeLe are summed up in table 1.

PeLe suits perfectly to evaluate both group dynamics and individual student results, it was primarily used in our research for *formative assessment* or low stake assessment which serves to give learners feedback on their performance (Sambell, 2010).

METHODOLOGY

Research Objectives

Mobile Language Learning (MOBILL) was an international project involving two institutions Sør-Trøndelag University College (HiST, Norway),

Table 1. Technological characteristics and the pedagogical potential of PeLe

Technological Characteristics of PeLe	Pedagogical Potential
Multiple choice tests can be delivered either via PeLe or in the written form	• Teaching in technologically limited environments • No need for profound tech preparation
Instant visualization of the test results	• Group dynamics evaluation • Formative assessment approach • Enhance learner motivation
Immediate test assessment and feedback	• Timely diagnosis of teaching/learning problems • Instant feedback on learning problems • Revision of teaching strategies
Student Response System is installed	• Can be used to conduct in-class surveys • Encourage peer discussions and post-test activities
Database stores both group and individual results	• E-portfolio approach • Formative assessment approach • Evaluation of group dynamics
It returns individual feedback to students' mobile devices	• Individual approach to each student • E-Portfolio approach
Multiple-choice questions are a mixture of text and images	• Visualization of learning materials • Enhancing learner motivation
The teacher can see on his screen what is happening during the test	• Evaluation of student learning progress • Any aspect of student output is under control
Equipment necessary: one internet-enabled teacher computer and internet-enabled student mobile devices	• Teaching in technologically limited environments • No need for bulky costly equipment
Use of student own devices	• No need for tech instructions - familiar devices

and Lomonosov Moscow State University (LMSU, Russia). The project was conducted during two periods from September 2013 to January 2014, and from February to May 2014. The key objective of this research was to work out sound pedagogical strategies on how to implement PeLe into the traditional language classroom (pedagogical perspective), thus introducing some improvements to the piloting tool (technological perspective). At the first period teachers from LMSU and HiST piloted PeLe and try to develop Mobile Assisted Language Learning Model (MALLM) based on enquiry-based approach and formative assessment. The following research questions were proposed:

1. What is the PeLe pedagogical potential to develop student language skills?
2. Does PeLe intervention impact assessment patterns of the traditional classroom and foster the development of learner language skills?

3. How can enquiry-based methods be effectively implemented into MALLM?
4. Does the proposed MALLM impact student motivation and to what extend?

THE PROJECT IMPLEMENTATION AND RESEARCH DESIGN: METHODOLOGY OF PELE INTERVENTION

The methodological framework of the MALL model based on PeLe implementation includes both enquiry-based methods such as collaborative and peer learning post-test activities, brainstorming, problem-solving activities, group discussions and mobile learning opportunities such as immediate feedback, formative assessment, and interactivity. We offered the following procedure of PeLe intervention employed in this study:

1. Setting up the Assessment Template

The teacher sets up the PeLe assessment template choosing the number of questions, alternatives, and the correct answer. In this case the teacher has three options: he can use the printed version of the test, he can show the test on the IWB or he can save the test on PeLe.

2. The Test is on.

Students take the multiple-choice test and the teacher gets the answers monitoring this process on his computer screen. When the students are picking up the correct answers using their devices the teacher can follow the group dynamics and each student test results. At this stage the teacher can see what kind of problems students have as a group and individually.

3. Test Submission and Instant Feedback

The teacher takes some time (usually about 3-4 minutes) to analyze test results, then students are shown their group scores on each test item in the form of a diagram. The teacher chooses the items that were the most difficult ones for students. After that, the pedagogical agent selects scaffolding from the range of post-test activities: teacher explanation, a group discussion, a pair discussion or SRS-supported activity.

4. Post-Test Activities

The teacher has to pick up a post-test activity aimed at improving test results. The type of activity depends upon the group results on a test question.

We offered the following activities: teacher explanation, group discussion, pair discussion. To figure out what types of post-test activities were the most effective ones we asked the teachers to fill in the grids on post-test activities used after each test.

5. Second Voting on the Tough Questions

After post-test activities, students take the second vote on the discussed questions using either SRS installed or PeLe. At this stage, the teacher can also provide immediate feedback comparing and demonstrating group results of the first and second trial.

RESEARCH PARTICIPANTS

The project target groups consisted of Norwegian and Russian learners of English, all at approximately the same language level (B1) according to the Common European Framework for Languages (see table 2). In the first period of experimentation, students enrolled in a preparatory English course at LMSU were randomly assigned to 3 experimental groups (EXG) and 1 control group (CG). Students of the experimental groups took a series of PeLe supported formative tests as volunteers using handheld devices. The control group was tested by pen and paper method.

Table 2. The project target groups

	Group Size	Male	Female	Number of Formative Tests	Entrance test MS	Entrance Test Score SD
EXG 1	12	1	10	7	81	5,97
EXG 2	8	1	7	7	64	8,75
EXG 3	9	3	6	7	66	15.09
CG	7	0	7	0	60	7,09

DATA COLLECTION

Data collection was done in 3 cycles:

1. The intervention of PeLe tests as formative assessment tools from September to December 2013 in three experimental groups. Quantitative data of the first and the second voting of PeLe tests were analyzed by mean and standard deviation, students' t-test results. The grid on post-test activities used after each test were completed by the teachers of the experimental groups.
2. Quantitative data of the final tests were gathered in control and experimental groups to compare overall performance at the end of the semester, the data were analyzed by mean and standard deviation, t-test results.
3. The post-intervention questionnaire asks students to reflect on their attitude to PeLe integration. Qualitative data were gathered to help explain quantitative findings.

RESEARCH RESULTS AND DATA DISCUSSION

Cycle 1

In the first cycle, the students of the three experimental groups took PeLe multiple-choice grammar and vocabulary tests according to PeLe methodology intervention. In the experimental groups, formative Pele tests were provided in the form of in-class grammar and vocabulary tests. Students responded with their smart phones or tablets. They had access to PeLe tests by using Wi-Fi in class.

The students of the control group were taught in the traditional way, they took the placement and final tests for summative assessment, they were not supposed to take formative PeLe supported tests with immediate feedback on their results.

According to the methodology of PeLe intervention we collected the quantitative data on the results of the first voting (FV) and the results of the second voting (SV) of the experimental groups (EXG) and analyzed the results. To assess the magnitude of any significant changes following the intervention, effect sizes were calculated according to the methods of mathematical statistics - the standard deviation (SD) and mean score (MS) for each group (see table 3). Based on the calculations, we can conclude that the effectiveness of the formative tests increased after post-tests activities. These results indicated that there was a substantial improvement in group 2 and 3 where the entrance test mean scores were 64 and 66 correspondingly although there was not the so substantial improvement in group 1 where the entrance test mean result was much higher - 88. In other words, it turned out that PeLe supported approach was more beneficial in our case for the groups with lower language level: FV MS1= 56< SV MS1= 75, FV MS2 =57< SV MS2=77. Statistical differences between the first and second voting of the PeLe supported test in the experimental groups were assessed using student's t-test for independent samples, as appropriate. T-test results of the first and second voting in group 2 and group 3 statistically are quite significant: EXG2 T-test= 3,0512 EXG3 T-test=3,2342. For group 1 T-test is 0,5023, by conventional criteria, this difference is considered to be not statistically significant.

Table 3. The mean score, standard deviation, t-test of the first and second voting of the PeLe supported test in the experimental groups

	FV MS	SV MS	FV SD	SV SD	FV and SV T-Test
EXG1	85	87	7,9	8,05	0,5023
EXG2	56	75	13,11	10,17	3,0512
EXG3	57	77	14,44	8,40	3,2342

Our study demonstrated that the second voting results in the experimental groups were better than test results of the first trial. The main reasons for that could be immediate feedback on group test results and post-test activities offered by the teachers in the experimental groups. Hattie and Timperley (2007) emphasize that effective feedback needs to provide information that specifically relates to the task so that students can develop error detection strategies and use the feedback to tackle more challenging tasks.

To answer the third question of our research we tried to figure out, first, what kind of post-test activity led to any improvement in student performance so was the most efficient one, second, whether it was the correlation between the group item score and the type of activity offered by the instructor. Our grid data analysis demonstrated that on average in each group 5.125 activities were offered after each test. The most frequently used by the instructors activity was the class discussion - 48% of the activities offered, then comes teacher explanation - 32,5% of the activities offered, the least frequently used activity was group discussion activities - 19,5% of all the activities (see table 4).

Class discussions are likely to be used more frequently because for the instructors it was easier to be a class facilitator and to initiate discussions asking open-ended questions that provoke further discussion, stimulate deeper exploration and challenge student thinking, encouraging them to seek new ways to work with problems and situations. But in this case only carefully formulated questions

can stimulate the generation of ideas and interest in what students have to say, providing clues as to whether students are 'on track' (Kahn & O'Rourke, 2005). Whereas peer tuition approach seems to be very time and effort consuming on the part of the teacher. Although experimental language groups were not numerous so it was quite comfortable for the learners and the instructor to have a discussion. Peer-tuition approach in language classes might also be complicated due to the fact that the language of instruction was foreign for the learners.

Our data analysis demonstrated that the most efficient post-test activity was the class discussion because the increase in the second trial test results was significant. These increases were statistically more significant for group 2 $T\text{-test}=3,053$, $FV\ MS2=56 < SV\ MS2=75$, and for group 3 $T\text{-test}=3,2342$, $FV\ MS3=57 < SV\ MS3=77$. In each group 21 class discussion activities were used (see table 5). These results substantiate the value of group discussions for student understanding, confirming the significance of constructivist approach in mobile learning (Arnesen, Korpås, Hennissen, & Stav, 2013).

The next question we tried to figure out is the correlation between the group item score and the type of activity offered. Our grid data analysis demonstrated that if from 50% of the group members gave incorrect item answer the instructors preferred teacher explanation technique. If from 50 to 75% of the group members gave the correct item answer the instructors offered either pair or class discussion activities. In this case,

Table 4. Number and type of post-test activities

	Teacher Explanation		Class Discussion		Group Discussion		Total Number of Activities		The Average Number of Activities Per Group
	%	N	%	N	%	N	%	N	
EXG 1	34,4%	11	53,1%	17	12,5%	4	26%	32	5,125
EXG2	37,5%	18	43,8%	21	19,9%	9	39%	48	
EXG3	25,6%	11	48,8%	21	25,6%	11	35%	43	
All Groups	32,5%	40	48%	59	19,5%	24		123	

Table 5. Correlation between second voting test results and the post-activities offered

	SV MS	FV and SV T-Test	Number of post- test activities		
			Teacher Explanation	Class Discussion	Group Discussion
EXG 1	87	0,5023	11	17	4
EXG 2	75	3,0512	18	21	9
EXG 3	77	3,2342	11	21	11

the teacher choice depends on the two important considerations whether it is necessary to give some additional input to initiate the discussion and whether the chosen activity helped save the time assigned for the test and its discussion.

Cycle 2

The learners of both control and experimental groups were given the same placement and final tests. These tests were used for summative assessment. The overall mean scores were included to compare overall performance of the control and experimental groups after the implementation of the intervention. The data collected on the mean scores of the entrance and final tests in control and experimental groups suggest that introduction of PeLe tests helped improve academic performance in the experimental groups in mean results of final test (see table 6) whereas the control group demonstrated just a slight increase in mean scores (60>62). Statistical differences between the two tests were also assessed using Student's t-test for independent samples: t-test results in group 1 are 1.807, in group 2 - 2.6201, in group 3 - 1.2405. In the control group t-test is the lowest - 0,7025. These data suggest that the introduction of PeLe

supported approach helped improve student performance in all three experimental groups.

These results support our hypothesis that collaborative enquiry-based learning and educational opportunities provided by handheld devices formative assessment led to a significantly better exam performance of the students who took PeLe quizzes, compared to those who did not. The summative part of PeLe tests ensured a high completion rate, whereas the formative part provided students with prompt feedback and gave them information on what they needed to do to improve their performance (Voelkel, 2013). The increase in the overall exam results was encouraging, but not conclusive to show that only PeLe tests were beneficial. It could also be due to timely feedback on test results, collaborative post-test activities and administration of formative tests.

Cycle 3

At this cycle, an online survey was administered to elicit students' own perceptions of PeLe intervention. The quantitative data were supplemented by student feedback gained from a post-study questionnaire. The post-study questionnaire contains 11 questions aiming to get student views on the

Table 6. Final and entrance test results in control and experimental groups

GROUPS	Entrance Test MS	Entrance Test SD	Final Test MS	Final Test SD	T-TEST
EXG1	81	5.97	87	8.23	1.8027
EXG2	64	8.75	78	14.58	2.6201
EXG3	66	15.09	73	10.30	1.2405
CG	60	7.09	62	4.88	0,7025

Table 7. Results of the post-study questionnaire

	Strongly Agree	Agree	Disagree	Strongly Disagree	Median Score
1. Mobile devices are the best tools to be used for language practice	17	4	3	0	3,58
2. PeLe tests helped me understand the topic in focus	16	6	2	0	3,58
3. PeLe tests helped me get ready for midterm and final a lot	16	4	2	2	3,41
4. Instant feedback after PeLe tests was very supportive and encouraging for my learning	22	2	0	0	3,91
5. Post-test activities made me better understand grammar rules	14	6	4	0	3,41
6. Post-test activities were very helpful and timely	17	5	2	0	3,62
7. Re-voting on SRS after post-test activities helped me correct my mistakes	11	6	3	4	3,00
8. Activity switching kept me engaged in class	10	8	4	2	3,08
9. The use of mobile devices and tasks based on PeLe was fun and changed my attitude to learning	10	8	4	2	3,08
10. PeLe tests were frustrating, they complicated my learning a lot	0	0	4	20	1,16
11. PeLe based tests were motivating	16	6	2	0	3,58

strengths and weaknesses of PeLe intervention. The questionnaire was completed by 24 students (22 female, 2 male) of the experimental groups. Responses are provided in table 7.

In response to statement 1 and statement 2 students expressed high levels of satisfaction (3,58) with PeLe supported tests undertaken on mobile devices. The majority of students commented favorably on the fact that mobile tests helped them understand the topic in focus and get ready for midterms and final with responses to the second statement averaging.

The largely positive reaction to statements 3, 4, 5 and 6, where the mean scores were 3,41, 3,91, 3,41 and 3,62 respectively, emphasizes that immediate feedback on test results was very supportive and encouraging for student learning. Students appreciated the prompt feedback they got on their own understanding of material. In response to statement 7, the average was 3,00. The students were very positive about the fact that re-voting after post-test activities helped them correct their mistakes and promote reflection on

grammar practice. The positive reaction to statement 8, where the mean score was 3,08, indicates that activity switch approach kept the students involved. Statements 9,10 and 11 were designed to get students attitude to PeLe intervention. The majority of students claimed that the use of mobile devices was fun and changed their attitude to learning. It supports the idea that the availability of mobile devices that learners possess makes it an attractive supplement to other forms of teaching and learning a second language (Stockwell & Hubbard, 2013).

In reaction to statement 10, the majority of students disagree on the fact that PeLe tests were frustrating and complicated their learning a lot. The average for statement 11 was 3,58 proving the idea that formative assessment tests promote feedback that seeks to empower students to become motivated and committed to exercising more control over their own learning (Sambel, 2010).

Our findings suggest that students place heavy emphasis on the value of instant, timely feedback on their tests as well as on post-test activities

that stood them in good stead in improving their grammar skills. Despite the overall positive responses, there was also notable ambivalence: several respondents combined positive comments with criticisms. For example, answering statement 7 four students strongly disagreed with the idea that re-voting on tough test items after post-test activities helped them correct their mistakes and promote reflection on their grammar practice. Nonetheless, our analysis demonstrates clearly that the vast majority of students found PeLe implementation to be very appealing.

FUTURE RESEARCH DIRECTIONS

We hope that our research will provide some constructs for pedagogical thinking about enhancing MALL with new mobile-assisted assessment methodology. Formative assessment practice (Black & Wiliam, 2009) lay at the heart of the project's innovative pedagogic approach, so the approach offers a practical way of embodying assessment for language learning environments. Although mobile testing system Pele holds promise but more research is needed to determine its effects upon developing not only grammar skills but also some other skills such as speaking, writing, listening.

CONCLUSION

This research indicated that mobile apps integration into language learning could be efficient, especially if combined with enquiry-based and peer learning approaches and the pedagogical potential provided by mobile testing systems. The experimental results suggest that the MALLM approach combining m-learning and enquiry-based learning theory and formative assessment is most advisable. The research results supported our hypothesis that collaborative enquiry-based learning and educational opportunities provided by handheld devices formative assessment led

to a significantly better exam performance of the students who participated in formative PeLe quizzes, compared to those who did not.

KEY TERMS AND DEFINITIONS

Enquiry-Based Approach: a learner-centered approach that emphasizes higher order thinking skills.

Formative Assessment: monitors student learning to provide ongoing feedback that can be used by instructors to improve their teaching and by students to improve their learning.

Interactive Learning: is a pedagogical approach that incorporates social networking into course design and delivery.

MALL: mobile assisted language learning.

Mobile Learning: learning methods and materials that involve the use of mobile phones or handheld devices.

Mobile Testing System: mobile apps design specifically for testing skills and knowledge.

Summative Assessment: evaluates student learning at the end of an instructional unit by comparing it against some standard or benchmark.

Nominalizations in Requirements Engineering Natural Language Models

INTRODUCTION

The first activity of the development of a software system is to define its requirements. Requirements engineer must interact mainly with clients and users among other stakeholders (Macaulay, 1993). He or she has to understand the context in which the future system will act and he or she must carefully consider the reasons that conducted to the decision of developing such system. Requirements engineer's responsibilities include establishing a fluid communication with all stakeholders to produce reliable documents that will be used later in the software development process (Leite et al., 2004). Usually the culture, knowledge and skills of clients and users are rather different from those of the software development experts. As part of the communication with clients and users, the requirements engineer must clearly show them the characteristics of the software system that he or she is conceiving to attend clients and users' issues. Requirements Engineering process has two main activities: to understand the application domain, and to correctly define the services that the future software system will provide (Leite et al., 2004). As a general practice, both activities involve the development of models that describe such domain. It is also a common practice to develop such models in natural language to enhance the communication among stakeholders (Rolland & Ben Achour, 1998; Leite et al., 2004; Seiff et al.,

2009); however, this introduces some obstacles, such as ambiguity, incompleteness and poor information structuring (Zowghi & Gervasi, 2002; Berry & Kamsties, 2004; Leite et al., 2005; Doorn & Rida, 2009; Hadad et al., 2015). All of these inconveniences come from the natural language itself. As a consequence, Requirements Engineering has become more and more involved with linguistic considerations. Furthermore, it should be kept in mind that language conveys culture and knowledge (Nettle & Romaine, 2000; Fishman, 1999). Thereby, the terminology of clients and users holds application domain knowledge. Therefore, to document and to slightly formalize the relevant words or phrases heard from clients and users or read from documents is a valuable practice. In other words, creating a glossary of such terminology helps the Requirements Engineering process in two relevant ways: it eases the understanding of the application domain and it reduces the ambiguity of the oral communication with clients and users and the ambiguity of every produced document (Hadad, Doorn, & Kaplan, 2009).

However, the glossary construction itself introduces some drawbacks. The most important of these drawbacks, not yet treated, is the presence of nominalizations, either in the clients and users' terminology or in the produced glossary. The former is a possible source of ambiguity while the latter is a hint of an adequate or inadequate

DOI: 10.4018/978-1-5225-2255-3.ch445

creation of glossary symbols by the requirements engineer. Both may cause defects in the glossary. Nominalization refers to the construction of nouns from verbs or adjectives. Linguistic authors have largely studied nominalization in many languages such as English, French, German, Russian, Spanish, etc. (Alexiadou, 2001; Bisetto & Melloni, 2005; Grimshaw, 1990; Rothmayr, 2009; Rozwadowska, 1997). The simplest way to describe verb nominalization is by means of the phrase *action of and effect of*. In some cases, nominalization occurs only by *action of*; while in others only occurs by *effect of*.

In this chapter, the influence of nominalization on the quality of Requirements Engineering documents is analyzed. The requirements engineer should be aware of the substantial differences in meaning, that sometimes arise when using the nominal mode of a verb or its verbal mode, since the action and the effect of a verb nominalization may produce synonyms or even homonyms.

BACKGROUND

The work presented in this chapter is based on the lessons learned in several research projects where many study cases were created using Scenarios and Language Extended Lexicon (LEL) models (Leite et al., 1997; Leite et al., 2000; Leite et al., 2004). LEL is a glossary proposed by Leite and Franco (1993). Scenarios are structured natural language descriptions of situations that occur in the application domain (Leite et al., 2000).

The LEL is itself a glossary with roles and structure different from the usual ones. It is composed by a set of symbols, which are words or phrases peculiar and frequently used in the application domain. Each symbol is identified by a name or names. An acronym or an abbreviation may be also a name of a term, only if present in the application domain. In case of synonyms the more relevant name is used as the main key entry. Every symbol has two types of descriptions; this particular structure makes the difference with

other glossaries. The first type, called Notion, is the usual one and describes the denotation of the word or phrase, that is, it defines what the symbol is. The second, called Behavioral Response, describes the connotation of the word or phrase, that is, it describes how the symbol acts in the application domain; this description is not usually present in other glossaries and enriches the knowledge about the symbol and the context at hand. LEL symbols contain hypertext links pointing to directly related entries.

When the denotation of the term acquires several meanings, it indicates the existence of homonyms, which forces the creation of more than one entry in the lexicon. The absence of any behavioral response indicates that the symbol does not belong to the LEL.

LEL entries are classified in four types according to its general use in the application domain. The types are: Subject, Object, Verb and State. Table 1 shows the LEL model.

Symbols of type object, verb and state may be affected by a linguistic transformation, called nominalization, which may hide the type of the symbol and may produce confusions between verbs and objects, or between verbs and states. Nominalization is a source of ambiguities, especially in behavioral responses. It has not received the necessary attention in the Requirements Engineering literature (Berry & Kamsties, 2004; Kovitz,

Table 1. Language EXTENDED LEXICON model

LEL: representation of the symbols in the application domain language. Syntax: {Symbol} _i ^N
Symbol: entry of the lexicon that has a special meaning in the application domain. Syntax: {Name} _i ^N + {Notion} _i ^N + {Behavioral Response} _i ^N
Name: identification of the symbol. More than one represents synonyms. Syntax: Word Phrase
Notion: denotation of the symbol. Syntax: Sentence
Behavioral Response: connotation of the symbol. Syntax: Sentence

Source: (Leite et al., 2000)

1998). This chapter is devoted to analyze and control the influence of nominalization on the quality of Requirements Engineering documents. Proposals to reduce the possible negative influence of nominalization are described.

The scenario model is a structure composed of the entities: title, goal, context, resources, actors, episodes, exceptions and the attribute constraint (see Table 2). Actors and resources are an enumeration. Title, goal, context and exceptions are declarative sentences while episodes are a set of sentences expressed in a simple language that give an operational description of behavior. A scenario must satisfy a goal that is reached by performing its episodes. Episodes represent the main course of action but they include also variations or possible alternatives. While performing episodes an exception may arise, signaling an obstacle to goal achievement. The treatment of the exception may or may not satisfy the original goal. All descriptions in the Scenario must maximize the use of LEL symbols, as a way to reduce ambiguity. This is another reason that strengthens the necessity of a high quality LEL creation.

VERB NOMINALIZATIONS

Verb nominalization may be interpreted as *eventive* with the semantic of *action of* and *stative* when it takes the semantic of *effect of*. Eventive nominalizations denote an activity and they are frequently combined with indications of location, duration or date. Eventive nominalizations inherit the arguments of the verbal base in such a way that they are capable of expressing the same semantic roles that the verb itself. Stative nominalizations are related with the result of the action of the verb. In most cases this result is an entity or a state. The following sentences contain the nominalization of the verb *publish*. The first sentence contains an eventive nominalization and the second a stative one.

- The software system must register the number of copies of every *publication*.
- The *publication* of books, and even of journals, requires resources that have to be available on time in order to minimize costs.

Ambiguity, completeness, and structuring of natural language documents are related among them. A slightly formalized glossary contributes to improve completeness since it contains a set of application domain notions materialized through subjects, objects, activities and states and their interrelations. The perception by the requirements engineer of any of those glossary elements helps to discover more information about the related glossary symbols. This clearly contributes to reduce incompleteness.

The experience acquired along many study cases led to observe the weaknesses that occur by nominalization of verb symbols. The semantic flaws produced due to nominalizations are of such nature that sometimes is quite different to register the verb itself or its nominalization in the LEL. The actual alternatives of verb nominalization may be:

1. Verb and its nominalization have exactly the same meaning.
2. Verb and its nominalization have different meaning.
 - a. Just verb semantic is relevant in the application domain.
 - b. Just nominalization semantic is relevant in the application domain.
 - c. Both verb and its nominalization semantic are relevant in the application domain.
3. There is more than one nominalization for the same verb.

The purpose of the LEL is to represent the vocabulary used in the application domain, therefore, nominalizations could appear or not as part of

Table 2. Scenario model

Scenario: description of a situation in the application domain. Syntax: Title + Goal + Context + {Resources}₁^N + {Actors}₁^N + {Episodes}₂^N + {Exceptions}
Title: identification of the scenario. In the case of a sub-scenario, the title is the same as the episode sentence (see below in the Episode definition), without the constraints. Syntax: Phrase ([Actor Resource] + Verb + Predicate)
Goal: aim to be reached in the application domain. The scenario describes the achievement of the goal. Syntax: [Actor Resource] + Verb + Predicate
Context: composed by at least one of the following sub-components: Geographical Location: physical set of the scenario. Temporal Location: time specification for the scenario development. Precondition: initial state of the scenario. Syntax: {Geographical Location} + {Temporal Location} + {Precondition} where Geographical Location is: Phrase + {Constraint} where Temporal Location is: Phrase + {Constraint} where Precondition is: [Subject Actor Resource] + Verb + Predicate + {Constraint}
Resources: relevant physical elements or information that must be available in the scenario. Syntax: Name + {Constraint}
Actors: persons, devices or organisation structures that have a role in the scenario. Syntax: Name
Episodes: set of actions that details the scenario and provides its behaviour. An episode can also be described as a scenario. Syntax (using partial BNF): <episodes>::= <group series> <episode series> <group series>::= <group> <group> <non-sequential group> <group series> <group> <group>::= <sequential group> <non-sequential group> <sequential group>::= <basic sentence> <sequential group> <basic sentence> <non-sequential group>::= # <episode series> # <episode series>::= <basic sentence> <basic sentence> <episode series> <basic sentence> <basic sentence>::= <simple sentence> <conditional sentence> <optional sentence> <simple sentence>::= <episode sentence> CR <conditional sentence>::= IF <condition> THEN <episode sentence> CR <optional sentence>::= [<episode sentence>] CR where <episode sentence> is described: ((([Actor Resource] + Verb + Predicate) ([Actor Resource] + [Verb] + Title)) + {Constraint})
Exceptions: usually reflect the lack or malfunction of a necessary resource. An exception hinders the achievement of the scenario goal. The treatment of the exception may be expressed through other scenario. Syntax: Cause [(Solution)] where Cause is: Phrase ([Subject Actor Resource] + Verb + Predicate) where Solution is: Title
Constraint: a scope or quality requirement referring to a given entity. It is an attribute of Resources, basic Episodes or sub-components of Context. Syntax: ([Subject Actor Resource] + Must [Not] + Verb + Predicate) Phrase
+ means composition, {x} means zero or more occurrences of x, () is used for grouping, stands for or and [x] denotes that x is optional

that vocabulary. Nominalizations are not a problem provoked by the Requirements Engineering process or by the requirements engineer himself or herself. It is an obstacle that he or she must manage by identifying the variants of the term

and by establishing the meaning of those variants in the application domain. When capturing the vocabulary used in the application domain, it could happen and it usually happens that the requirements engineer does not perceive one or

more of the possible meanings of a nominalized verb. Once this happens, it is very likely that he or she describes only the captured meaning keeping all the omissions undiscovered.

SOLUTIONS AND RECOMMENDATIONS

Each one of the cases enumerated in the previous section should be treated in a particular way, as shown in Table 3. When the requirements engineer runs across with a verb symbol, he or she does not know in which case the verb falls. To avoid omissions or ambiguities he or she has to find out how the symbol is used in the application domain, and then to which case it belongs in order to take out the correct action.

Table 3 strictly considers the possible consequences of the use of nominalizations without paying attention to the particular semantic of the verb itself or its nominalizations. Actually a verb or a nominalization may have more than one interpretation in the application domain, producing eventually homonyms. Therefore, any of the cells of third column of Table 2 may produce more symbols than it is indicated. Watching how the nominalizations are used is not enough to detect such additional homonyms cases. This happens with any single symbol of the LEL, regardless if it is the nominalization of a verb or not. The particular semantic of each symbol should be clearly understood in order to discover hidden or partially hidden homonyms, and possible synonyms.

Table 4 shows an example about the Study Case Production Management of Cardboard Boxes. In

Table 3. Guidelines to manage verbs and nominalizations

Syntactic Form	Meaning	Action
Used as a verb	Action of	Register as a verb symbol
	Effect of	N/A
	Both	N/A
Used as a nominalization	Action of	Register as a verb symbol
	Effect of	Register as an object or state symbol
	Both	Register both as a verb symbol and as an object or state symbol. Label both as homonyms
Used as a nominalization with more than one nominalization	Action of	Register each of them as a verb symbols. Consider that eventually any nominalization may be a synonym of another
	Effect of	Register each of them as object or state symbols. Consider that eventually any nominalization may be a synonym of another
	Both	Register as a verb symbol and as an object or state symbols. Consider that eventually any nominalization may be a synonym of another
Used both forms	Action of	Register both forms as a verb symbol, choose the most used form as key entry name and the least used as synonym (see Table 3)
	Effect of	N/A
	Both	Register both as a verb symbol and as an object or state symbol (see Table 4). Consider that the nominalization may be also a synonym of the verb form, then label both entries as homonyms
Used both forms with more than one nominalization	Action of	Register all forms as verb symbols. Consider that any nominalization may be a synonym of the verb form; choose the most used form as the key entry name and the other as synonym. Label homonyms if applicable
	Effect of	N/A
	Both	Register as a verb symbol and as object or state symbols. Consider that one of the nominalizations may be a synonym of the verb form; choose the most used form as the key entry name and the other as synonym. Consider that eventually any nominalization may be a synonym of another. Label homonyms if applicable (see Table 5)

Table 4. Verb and its nominalization used as action of, being both synonyms; Study Case: Production management of cardboard boxes

Symbol Name/s	Plan Production / Production Planning	Type: Verb
Notion	• Process to establish the <i>production schedule</i> for all the shifts of the next week. • It is performed every Tuesday.	
Behavioral Response	• <i>Manufacturing programs</i> for each of the 21 shifts per week are generated. • Deployments boxes are organized to <i>reduce cardboard scrap</i>. • <i>Production orders</i> received from a <i>collaborative supplier</i> are considered <i>urgent orders</i>.	

this example, the requirements engineer detects two different synonyms, used both in that context, for the same action: Plan Production and Production Planning.

In Table 5 there are two different symbols, one is a Verb symbol, Pay, and the other is an Object symbol, Payment, belonging to the same study case, Management of Treatments given by Medical Providers, where the Object refers to the verb nominalization used as effect of.

In Table 6 the symbol Authorize Treatment is a Verb, and there are three different nominalizations. The first one, Treatment Authorization, is a synonym of Authorize Treatment, being both verbs. Treatment Authorization as a Verb is also the homonym of Treatment Authorization as an Object. The third nominalization has generated a State symbol Authorized Treatment.

FUTURE RESEARCH DIRECTIONS

This chapter presents the results of an exploratory research which has allowed discovering, as a regular pattern, the presence of many nominalizations of verbs that are relevant in the application domain. Frequently, such nominalizations have created different types of defects in the glossaries. The knowledge of the existence of those defects and the understanding of their cause has allowed proposing guidelines in order to reduce quantitative and qualitative consequences of such defects. These guidelines have been proven to be effective in few and small study cases. It is planned to perform a set of more structured experiments to quantify the efficiency of the proposed guidelines and to obtain reliable statistics and metrics of the quality enhancement of the glossaries and the importance of this on the whole Requirements Engineering process.

Table 5. Verb and its nominalization used as effect of; Study Case: Management of treatments given by medical providers

Symbol Name/s	Pay	Type: Verb
Notion	• Action performed by the <i>treasury staff</i> producing an economic compensation to a <i>medical provider</i>. • It takes place after the <i>payment</i> has been approved by the <i>medical director</i>.	
Behavioral Response	• The <i>treasury staff</i> issues the <i>payment</i> thru the <i>system</i>. • The <i>treasury staff</i> notifies the <i>medical provider</i> upon the issued <i>payment</i>.	
Symbol Name/s	Payment	Type: Object
Notion	• Document issued by the <i>treasury staff</i>, establishing the cancellation of a debt acquired due to a <i>treatment</i> given by a <i>medical provider</i>.	
Behavioral Response	• It is registered in the system. • It requires the <i>director</i> approval before given to the <i>medical provider</i>. • A copy signed by the <i>medical provider</i> is stored.	

Table 6. Verb and two nominalizations used as action of and effect of, producing synonyms and homonyms; Study Case: Management of treatments given by medical providers

Symbol Name/s	Authorize Treatment / Treatment Authorization	Type: Verb
Notion	• Action that allows the <i>patient</i> to receive <i>treatment</i>. • It is performed at the <i>patient service office</i>.	
Behavioral Response	• The staff checks the <i>medical credit</i> of the <i>patient</i> thru the <i>system</i>. • The staff checks the <i>clinical order</i> given by the <i>patient</i>. • The staff issues an <i>authorization</i>. • The staff delivers the <i>authorization</i> to the <i>patient</i>. • The <i>patient</i> annexes the <i>clinical order</i> to the <i>authorization form</i> in order to get its <i>treatment</i>.	
Symbol Name/s	Treatment Authorization / Authorization	Type: Object
Notion	• Document issued by the <i>patient service staff</i>, allowing a <i>patient</i> to get a <i>treatment</i>.	
Behavioral Response	• It is generated thru the <i>system</i> based on the <i>clinical order</i> exhibited by the <i>patient</i>. • It is signed by the <i>service director</i>. • It is assigned a sequential number and an expiration date.	
Symbol Name/s	Authorized Treatment	Type: State
Notion	• Condition that a <i>treatment</i> takes after <i>treatment authorization</i>.	
Behavioral Response	• The <i>patient</i> can get a <i>treatment</i> thru a <i>medical provider</i> before its expiration date. • After the <i>patient</i> gets the <i>treatment</i>, the <i>medical provider</i> issues an <i>invoice</i> to receive the <i>payment</i>.	

CONCLUSION

The research whose results are reported in this chapter may be summarized as:

- The relevant words and phrases of any application domain include several verbs.
- The full understanding of the verbs is important for improving the knowledge about the application domain.
- Nominalization of verbs obscures the perception of their eventive or stative semantic.
- Frequently one of the possible verb nominalizations hides the perception of the others.
- Losing an eventive or a stative meaning prevents discovering important information.

L

KEY TERMS AND DEFINITIONS

Ambiguity: Phrase or sentence that does not have a single clear meaning. It provokes two or more possible interpretations.

Application Domain: The context in which the software system will be used.

Completeness: The state or condition of having all the necessary or appropriate parts of a model or document.

Language Extended Lexicon: A glossary composed by a set of symbols, which are words or phrases peculiar and frequently used in a given application domain. The lexicon symbols have an additional description, not present in other glossaries. It contains hypertext links that interconnect symbols.

Natural Language Model: A model in narrative text produced during Requirements Engineering process, with a structure and content easily read by all stakeholders.

Nominalization: The result of forming a noun from a verb, or the act of forming a noun from a verb. Nominalization itself is the nominalization of the verb *nominalize*. In this chapter it is used as a verb and as the effect of the verb (a state).

Omission: Information that has not been included in a model or document. It is the nominalization of the verb *omit*. In this chapter it is used as the effect of the verb (a state).

Scenario: The description of a situation that currently happens or will happen in the application domain. The former are called Current Scenarios and the latter are referred as Future Scenarios.

Word Formation Study in Developing Naming Guidelines in the Translation of English Medical Terms Into Persian

Ali Akbar Zeinali

Universiti Sains Malaysia, Malaysia

INTRODUCTION

The medical translation is a critical tool for communication between patients and health care professionals. A correct translation finds itself significant when a medical translator, as a skilled mediator, acts accurately and precisely by transferring the messages between a medical professional and a patient. This study is of utmost importance as it aims to find guidelines specific to translation procedures of English medical terms into Persian through word formation processes for linguists and translators. Such guidelines can be employed by translators to find the required equivalents. Persian linguists from the Persian Language and Literature Academy (PLLA) and Medical Science Academy in Iran may also find it beneficial. It may be effective and applicable to information technology and machine translation systems linguistic databases. This study presents the findings obtained by a comparative analysis of the Persian translation equivalents found in “اهیرامی بی لملل نی ب یراذگدک یامنهار” (Guide to ICD-9-CM in Persian) using the universal naming guidelines and local naming principles in Persian, with regard to their pairs in English selected from medical terms in “ICD-9-CM.” The study went through the research questions to investigate the naming characteristics of the English-Persian medical terms with respect to Sager’s criteria (1990, p. 88) who provides 12 criteria for the perfect idealized requirement in a serious controlled condition for naming, the PLLA principles, the effectiveness of the adopted TPs in naming, the contribution of the morphosemantic

DOI: 10.4018/978-1-5225-2255-3.ch446

factors to the naming process and to propose the specific naming parameters for the translation of English-Persian medical terms. The objectives of the study were also in line with the research questions. The analysis focused on Sager’s naming criteria, the PLLA naming principles, and the applied translation procedures on the selected English medical terms into Persian equivalents during the translation process.

BACKGROUND

According to Ashuri (1995, p.29), one of the problems for Persian today is the fact that it is a combination of ancient writings and translation works. Scientific language of new works mostly deals with translation together with a lot of English and French words and syntactical structures. He suggests that the word formation is a solution for enriching a language with new concepts.

Beheshti (1999, pp.25-31) explains that one of the most significant contemporary linguistic issues is scientific-technical word formation, which is based on the language grammar and linguistic principles. She discovered that only 50 percent of the total terms studied had the equivalences in Persian; thus, indicating that the translators have not yet shown interest in employing Persian equivalents in their works. Further investigation is crucial to uncover the underlying reason. According to her, equivalent findings or naming of imported medical terms should be based on the features specific to medical terms. This means that medical terms, either in the source language

or the target language, should be studied to find their systematic characteristics and some patterns in order to help the translators or linguists in the word formatting process or naming imported terms in the future. She suggests a study on the patterns based on the term characteristics of morphology, etymology, word formation and translation procedures.

Naseri et al. (2011, pp.41- 47) believe that the present problems of Persian in the areas of science and technology are due to the application of foreign language structures, lack of consistencies in scientific terms, and no consensus among authors and translators. Sadeqi (1993) believes that the solution to these problems is stabilizing the scientific and technical terminology at the basic levels and mass media. He states that the scientific terminologies are not consistent and in some cases, there are various Persian equivalents for a single foreign word in different dictionaries, or there are various foreign equivalents for a single Persian word. As a result, it is claimed that the scientific expressions are inconsistent (Kafi, 1992). According to Beheshti (1999, p.31), a language that borrows a large number of words suffers from negative consequences in the general language and can denigrate the capacity for people to speak their native language (i.e. such as German language in interaction with the English language). The Persian language in interaction with other languages will lose its capabilities and will be converted to a totally different language if it is not protected against the foreign words imported from many languages. Therefore, activating the Persian language capabilities for naming the scientific and non-scientific foreign words is considered as a necessity which should be based on definite principles or patterns.

MAIN FOCUS

It is of the interest of this study to investigate what types of universal naming criteria and principles are followed by the selected data. While naming

process should follow the international naming guidelines, the state or local naming principles may not be skipped, as creation of an equivalent in the target language should be lexically and semantically based on the cultural, terminological, linguistic and language factors of the target language.

The naming criteria suggested by Sager (1990, p.88) provides guidance on the creation of terms to be referred to when the translator deals with the difficulties in coining translated terms because of different structures and term formation techniques found in various languages. It remains difficult to generalize on a broad level. Sager provides 12 criteria for the perfect idealized requirement in a serious controlled condition for naming. "Criterion" is abbreviated as "C" in this study and it is followed by a numerical digit showing the number of criterion suggested by Sager. For example, "C1" represents the first criterion Sager has proposed for term formation. These criteria are outlined as below:

- C1. The term must relate directly to the concept.
It must express the concept clearly. A logical construction is advisable.
- C2. The term must be lexically systematic. It must follow an existing lexical pattern and if the words are of foreign origin, a uniform transcription must be preserved.
- C3. The term must conform to the general rules of word formation of the language which will also dictate the word order in compounds and phrases.
- C4. Term should be capable of providing derivatives.
- C5. Terms should not be pleonastic (i.e. no redundant repetition, e.g. combining a foreign word with a native word having the same meaning).
- C6. Without sacrificing precision, terms should be concise and not contain unnecessary information.
- C7. There should be no synonyms whether absolute, relative or apparent.

- C8. Terms should not have morphological variants.
- C9. Terms should not have homonyms.
- C10. Terms should be monosemic.
- C11. The content of the terms should be precise and not overlap in meaning with other terms.
- C12. The meaning of the terms should be independent of context.

In this study, Persian word formation structures will be processed according to the Naming Guidelines approved by the Persian Language and Literature Academy (2009). These principles, obligatory for the word formation teams, have been approved by PLLA, as word designation and equivalent findings for the imported terms are the concerns of the Academy according to Article 2 and 3 of the second provision of the Islamic Republic of Iran constitution. "Principle" is abbreviated by "P" which is followed by a numerical digit showing the Principle number approved by PLLA. For example, "P2" is the second principle which is proposed by PLLA for naming. PLLA provides nine principles for naming which are outlined as below:

- P1. Persian words should be based on "basic Persian language today" i.e. the common language used by the learnt societies.
- P2. Word designation should adhere to the correct grammar structure of the Persian language.
- P3. Word designation should avoid dissonance and cacophony and should be based on Persian phonetics. As a result, the designated word, as much as possible, should be shorter than its pair in the source language.
- P4. Equivalents with derivational and inflectional capabilities and also words with noun, adjective and verb possibilities are required to determine word designation priorities.
- P5. Word designation should consider the following hierarchy as criteria:
 - P5.1 Older common and accustomed words in the Persian language

- P5.2 Neologisms according to Persian word formation processes using Persian words
- P5.3 Arabic words, common and accustomed in the Persian language
- P5.4 Neologisms according to Persian word formation processes using Arabic words common in the Persian language
- P5.5 Words borrowed from several Persian language dialects in Iran today
- P5.6 Words borrowed from medieval and ancient Persian Languages
- P6. In word designation, the priority is given to the words with clear meaning compared to the ones with ambiguous meaning.
- P7. In word designation, especially in scientific areas, one word should be designed for any word with special meaning regardless of any probable diversity.
 - Nota bene: Designation of multiple equivalents is applicable for any foreign word with several scientific definitions, according to scientific tradition, history and convention.
- P8. No equivalent is needed for foreign words that are universally known and accepted.
- P9. The Language Academy Council will make the final decision in case of failure in word designation process based on common Persian language patterns.

Based on a comparison between the Persian medical equivalents with Sager's naming criteria and the PLLA naming principles, the goal of the study is to determine the similarities and differences of the compatible and incompatible terms (Persian equivalents) with respect to the applied translation procedures and the applied word formation processes and to identify those with the highest number of frequencies.

The compatible and incompatible equivalents with Sager's criteria and the PLLA Principles provide the data for this study and enable statistical descriptive and qualitative analysis to be carried

out. The collected data included a population of 339 Persian medical terms from the target text with regard to their pairs from the source text, which is sufficient with respect to the statistical descriptive method of analysis. It should, however, be noted that the selected terms reflected only the results limited to the selected system of the human body (the musculoskeletal system and connective tissue). Furthermore, the results obtained in this study do not necessarily reflect all the guidelines available for the translation of all the medical terms of other human body systems mentioned in ICD-9-CM into Persian.

This study establishes a conclusion about the integration of the findings of the study. It begins with a discussion of inferences drawn from the study and is followed by a comparative description of the findings and recommendations.

Data Analysis and Methods

The study needs preliminary information for analyzing the data including grammar, morphology, etymology and syntax. The Persian term will be broken down into components or morphemes based on the Katamba morphology (1994) and Tabatabaee's structures (2009). The analysis will focus on the characteristics of the Persian terms in accordance to the naming guidelines provided by ISO and criteria suggested by Sager (1990, p.88). The terms will subsequently be processed based on the principles recommended by the PLLA.

This is designed to uncover the fact that those English medical terms with certain characteristics can be translated through certain translation procedures and word formation processes and are compatible with certain Persian word formation patterns. It should be noted that in this research, a positive or compatible equivalent indicates the positive compatibility of the equivalent with all the PLLA principles and Sager's criteria; and a negative or incompatible equivalent indicates negative

or no compatibility of the equivalent with at least one of the PLLA principles or Sager's criteria. The conclusion will be uncovering the effective naming parameters or patterns for translating the medical terms from English into Persian.

The analysis of each term from the source language and its pair in the target language is performed according to the arranged elements of a data table (Table 1). For better explanation, suppose that the term *ازولانی* [azolāni ostoxāni] has been selected among the related terms of the selected system of the human body in the target text.

Among the selected terms, a few have equivalents that are composed of two separate words, one with borrowing and derivation processes and the other with only the derivation process. As in the example, the single Greco-Latin term of "musculoskeletal" (Dorland's Medical Dictionary, 2005) is composed of two free root words of "musculus" and "skeleton" which have been embedded by the derivational Latin suffix "al". Like other examples of this group of terms, the equivalent consists of two separate words, *ازولانی* [azolāni] /azola:nI/ (muscular), which is Arabic, and *استوخانی* [ostoxāni] /ostoxa:nI/ (skeletal), which is Persian. The former matches with the borrowing process, while the latter is a native word in the target language. Both of them indicate derivation in their word formation processes as well. The suffix "i" as an adjectival suffix is observed in both Persian words. In Persian, it is not possible to combine the two words together by adding the suffix only to one of them, so the translator is required to produce two independent adjective words which do not make a phrase. In this example the translation procedure is through translation since "musculoskeletal" is a compound word.

Table 1 shows the analysis of the equivalent produced and it could be concluded that this compound equivalent is not applicable due to its unconformity to Sager's 7 and 8 criteria and

Table 1. Data table

English Term		Musculoskeletal	
Equivalent in Persian		عضلانی و استخوانی (azolāni + ostoxāni)	
Gloss		muscular + skeletal	
Back Translation		muscular-skeletal	
Parts of Speech		adjective	
Morphological Analysis		azolāni [muscular]	ostoxān+i [skeletal]
		root	root + suffix
Parts of Speech		adjective	adjective
Tabatabaee's Persian Structure		balanced structure Adj+ - + Adj. = Adj	
Morphosyntactic Structure		Adj + Adj	
Word Formation		(borrowing, derivation) + derivation	
Translation Procedure		through translation + substitution	
Sager's Criteria		PLLA Principles	
Result		Result	

mismatches with principle 7 in naming Principles of PLLA. However, it indicates that there is a compatible structure with the Balanced Structure of Tabatabaee's structures i.e. adj + - + adj.

The problem with the above example is multiplicity. With respect to Sager's criteria 7 and 8, it is found that another synonym like [azole i] "عضلانی" (muscular) can be used that follows the Persian structure, i.e. [azole] (root) + i (adjectival suffix), while [azole] "عضله" (muscle) is borrowed from Arabic as an independent word. On the other hand, [azolāni] "عضلانی" is also imported from Arabic as an independent adjective. Since [azolāni] is an Arabic adjective, it cannot be matched with any Persian structure, because there is no [āni] suffix in Persian structures that can combine the borrowed noun [azole]. Thus, no derivability can be found for [azolāni] as it is an adjective imported directly from another language. It violates principle 7 in the naming PLLA principles.

Findings

The findings of the equivalents under this study can be classified into two groups: compatible

and incompatible equivalents. The compatible terms are the ones which follow all of Sager's criteria together with all of the PLLA principles. These terms or words are compatible with all the requirements for naming. In other words, the compatible terms automatically present those features of translation procedures which are effective for naming the Persian medical terms. The incompatible terms are the ones which do not follow one or more naming criteria suggested by Sager or the naming principles recommended by the PLLA. Such terms or words are incompatible with all or some of the naming requirements for naming. In other words, the incompatible terms automatically present those features of translation procedures which are ineffective for naming the Persian medical terms. Table 2 indicates the frequency of distribution for these two groups of equivalents under this study.

The study identified that around 67% of the terms are incompatible with the basal naming guidelines employed in the study (Figure 1). Generally, the findings of this study are not limited to the incompatible equivalents, but to the compatible ones also. The compatible equivalents can indicate

Table 2. Frequency and percentage of the compatible and incompatible equivalents

Equivalents	Frequency	Percent
Compatibles	112	33.04
Incompatibles	227	66.96
Total	339	100

the effective translation procedures and naming requirements for the secondary word formation of English medical terms into Persian. According to Sager (1990, pp.80-83), the terms which belong to scientific and technological innovations basically differ from the terms accompanying the transfer of scientific and technological knowledge from one linguistic society to another: “while the former is spontaneous, the latter can be designed and engineered”. Primary term formation is a process starting with concept formation in a scientific area. Such a process is out of external control, and is therefore monolingual and affected by “existing patterns of terms already created”.

The incompatible ones illustrate the incorrect methods which should not be followed in the translation processes; however, they can be changed to compatible ones by employing the guidelines provided through this study. The incompatible

frequencies, as well as the applied translation procedures, are important findings of this research and will be discussed in the next sections.

Compatible Terms or Equivalents

The finding shows that Criteria 10, 11 and 12 (C10, C11 and C12) are the criteria which are fulfilled by the terms in this study. It means that firstly, all the equivalents under this study follow some semantic criteria. Secondly, the respective terms belong to one meaning each and the meaning does not overlap with other terms; and thirdly their meanings can be learnt out of context.

Given the PLLA principles, the compatible principles that resulted in the equivalents in this study are principles 1, 5, 8 and 9 (P1, P5, P8 and P9). Based on the analysis, all equivalents in this study have been formed in the Persian language area today, and they follow the regularities of word designation discussed in P5. Principles 8 and 9 are items suggested by PLLA to help the translators and linguists in case of inquiry. Principle 5 has been classified in lexicology category. As all equivalents in this study are compatible with P5, some of the terms are conflicting with those principles suggested by PLLA in semantic area.

Figure 1. Distribution of the compatible and incompatible equivalents

On the other hand, some equivalents are totally compatible with all Sager's criteria and the PLLA principles. Those terms are formed by through translation procedure of the ones classified by Newmark (1988, p.81) including transference, naturalization, through translation, shift, modulation, recognized translation, literal translation etc. For some terms, substitution and naturalization have been identified as the translation procedures, and they are utilized in the translation process, which lead the equivalents to be compatible with all basal guidelines. It indicates that through translation and naturalization are two effective procedures in translating English medical terms into Persian if they are applied independently and are not combined with any other procedure.

Incompatible Terms or Equivalents

The most incompatible equivalents have been found the ones which do not fulfill the Sager's criteria 4 and 7 together with principle 3 of the PLLA. Such terms, with a frequency of 54 occurrences, consists of 16% of the total terms and 26% of the incompatible terms in this study. The applied translation procedure in these equivalents include (substitution + shift + through translation) with 50 terms and (shift + through translation + naturalization) with 4 terms. It indicates that the majority of incompatibility in the equivalents belongs to (substitution + shift + through translation). Substitution is a translation procedure suggested by C. Heah (1989, p.191) in which borrowing is employed as a word formation process.

The study also found that the next high frequency of incompatibilities is related to the equivalents which do not fulfill criterion 4 and principle 3 with a frequency of 48 terms consisting of 14% of the total terms and 23% of the incompatible terms in this study. The applied translation procedures for these equivalents are (substitution + shift) with 40 terms and shift with 8 terms. It is clear that the second important area which is targeted by incompatibilities in this study is (substitution + shift).

Results

The finding of the current study is as below:

1. The equivalents in this study are more incompatible with the guidelines in the lexicology area compared to the semantics area.
2. With respect to Sager's criteria, around 52% of the equivalents have been constructed without any derivational capability (-C4).
3. With respect to the PLLA Principles, around 56% of the equivalents have translations that are longer than their pairs in the first language (-P7).
4. With respect to the applied translation procedures, most of the equivalents are incompatible with Sager's criteria and those equivalents are constructed by (substitution + shift + through translation) feature of translation procedures.
5. 22% of the terms mentioned in the previous item do not have any derivational capabilities (-C4) and 15% have at least one more or other synonym (-C7).
6. With respect to the applied translation procedures, around 33% of the equivalents constructed by (substitution + shift + through translation) feature of translation procedures are incompatible with the PLLA principles.
7. 22% of the terms mentioned in the previous item have longer translations than their pairs in the first language (-P3). This frequency has been repeated for terms without any derivational capability (-P4) and for those that have not been constructed with special meaning (-P7).
8. The medical Persian equivalents incompatible with C4 can be categorized into three categories:
 - a. Equivalents that have been constructed in a phrase pattern which do not leave any opportunity for derivational discussion. Such equivalents should be made into single nouns in derivational area and not into phrases.

- b. Equivalents that do not have any derivation in the source language term pair; therefore, there is no need to explain them in derivational area.
 - c. Equivalents that have been translated incorrectly by the translators which do not follow the derivational capability.
9. The main problem of incompatibility of Persian medical terms with Sager's criteria or the PLLA principles is due to borrowing and substitution procedures. Therefore, naming through word formation should be done carefully with respect to the compatibility with basal guidelines.

THE RECOMMENDED GUIDELINES SPECIFIC TO THE TRANSLATION OF ENGLISH MEDICAL TERMS INTO PERSIAN

The findings and discussions conducted the study to many guidelines specific to medical translation, providing facilities for English-Persian translation of medical terms. Although the current medical equivalents in Persian, either compatible or incompatible, are largely used in the Persian language society, the following guidelines recommended by this study, will be applicable as the rectification of the existing translation procedures and naming Persian medical equivalents in the future. The guidelines are as follows:

1. Through translation and naturalization are the translation procedures applicable in the translation of English medical terms into Persian if no other translation procedure is involved simultaneously and if the equivalent is a single word and not in a phrase structure.
2. The source language medical term which appears in the form of an adjective or a derived word can be translated into Persian by through translation or naturalization if no other translation procedure is involved simultaneously. In this case, the equivalent

- will be a single word with derivational capability in the form of a noun or adjective.
3. Substitution and through translation can be employed simultaneously to translate an English medical term into Persian if the equivalent is a single word with derivational capability.
 4. Naturalization and through translation procedures can be employed simultaneously in the translation process of an English medical term into Persian if the equivalent is a single word with derivational capability.
 5. In Persian which is a language without any combining form morphemes, the third principle of PLLA cannot be applied in the naming of words or in the word formation process of the medical terms, unless the combinational capability of the Persian language is modified.
 6. Obviously, derivational capability will not be discussed in the naming process of the Persian medical terms if the medical equivalent construction is conducted toward phrasal word formation. Therefore, C4 is not applicable in order to produce such terms or equivalents.
 7. If the (substitution + shift + through translation) feature is employed for the translation of English medical terms into Persian, for the component of the phrase which has been formed by substitution (or borrowing), the translation procedure should adhere to either Sager's criteria or the PLLA principle. Such situations can be observed for single-word English medical terms, while their equivalents are in phrase forms.
 8. If the constructed equivalent is a noun phrase, the translator should consider a single-word synonym as the 'illustrate' equivalent for derivational applications.

IMPLICATIONS

The ever-increasing number of imported words and specific terms into the native language is due to the rapid development of technology and science. It is challenging to find appropriate equivalents for terms or technical words because of the lack of effective translation guidelines applicable in the translation process. Research needs to be conducted to solve the problem. The goal of this study is to propose guidelines specific to translation procedures of English medical terms into the Persian language through term formation processes. If there is a specific guideline for naming the terms, translators will not seek equivalents based on individual preferences and there should be consensus within the field and this will reduce the discrepancy in establishing terminology equivalents. It will also be beneficial for Persian linguists from the PLLA and Medical Science Academy in Iran, as they can finally come across standardized and acceptable equivalents in Persian.

Borrowing several equivalents with different word origins for just one imported word illustrates that none of the available equivalents has been effectively adopted. The problems in scientific and technical language are due to imitating or borrowing language structures and grammar from several languages, which is the result of a lack of fixed or standardized scientific terminology or the disagreement among authors and translators (Sadeqi, 1993, pp.125-6).

Regarding the equivalents incompatible with either Sager's criteria or the PLLA principles, it should be emphasized that the problematic area for the translation process of the English medical terms into Persian has been identified by this study. However, this study highlights that caution needs to be exercised by translators or linguists not to adopt some features of translation procedures.

RECOMMENDATION FOR FURTHER STUDIES

This research focused on the study of one of the human body systems classified by ICD-9-CM. Future students, researchers, linguists and translators should conduct further investigations in other systems of the human body to find more comprehensive or universal results. Indeed, this study is considered a step towards recognizing any unknown problem in the medical translation process. Therefore, the following investigations and studies are recommended:

1. To find basic and general guidelines specific to the translation of English medical terms into Persian, further research is needed to include other human body systems. Comparing the findings and conclusions with the findings and conclusion of this study will allow us to have more reliable and fundamental translation approaches or naming guidelines.
2. Other languages, given their basic language characteristics, may follow this research methodology to identify their problems with translation of the English medical terms into their language, which will allow them to have effective guidelines.
3. The guidelines in this study may be applicable to those languages with characteristics similar to those of the Persian language, which need further investigation by related linguists, terminologists and translators.
4. This research style can be employed for the terms in other technological and scientific fields to find their potential problems with the translation process of the English terms into their equivalents in Persian, which suggests effective guidelines that are unique to the related field.
5. The guidelines in this study may be applicable to other technological and scientific fields, which depend on the source language and the target language (Persian).

6. The applied research methodology, the employed research style and the resulted guidelines in this study may be effective and applicable to information technology and machine translation systems linguistic databases.

CONCLUSION

In conclusion, this research attempts to look at this issue from the naming secondary term formation perspective based on the two basal guidelines and the translation procedures employed in translating medical terms from English into Persian and highlights the compatibility of the equivalents with respect to translation procedures and word formation processes, finding problematic areas and presenting guidelines unique to translation of English medical terms into Persian.

KEY TERMS AND DEFINITIONS

Cacophony: According to Encyclopedia Britannica, “cacophony”, the opposite of “euphony”, refers to combination of words that produce harsh discordance of sound. Linguistically, euphony and cacophony belong to the study of inherent pleasantness or unpleasantness of the sound of certain utterances. This knowledge is called “phonaesthet-

ics”. Morphologically, this word is derived from two Greek word parts that mean “voice-sound” and “aesthetics.” Despite cacophony, euphony is achieved through the use of vowel sounds in words. Vowel sounds, which are more easily pronounced than consonants, are more euphonic; the longer vowels are the most melodious. See dissonance.

Compatibility: In this study, the characteristics of the equivalents or terms will be investigated and discussed according to the compatibility status with Sager's criteria and the PLLA principles. In other words, it will be studied if the terms follow the naming guidelines (as compatible equivalents) or appear out of naming guidelines (as incompatible equivalents).

Effectiveness: “Effective” or “ineffective” are the terms which are employed in this study for the effectiveness of the applied translation procedures in the translation process of English medical terms into Persian. It is evaluated based on four terminological factors suggested by Meyer and Bowker (2006: p.117) which belong to morphosemantics in linguistics. Conciseness, absence of competing terms, derivative form capability, and compliance with the rules of the language are the four factors that can all contribute to the effectiveness of the applied translation procedures in translating the English medical terms into Persian.

Morphosemantics: Morphosemantics is generally a knowledge in linguistics, pertaining to morphological analysis combined with a semantic interpretation of words.

Naming Guidelines: It refers to the criteria or principles which should be followed in naming or word designation process. Naming guidelines can be categorized into the ones which are common for all the languages around the world, namely universal or international guidelines, and the ones which are specific to a certain language society namely local guidelines.

Naming / Word Designation Process: Naming occurs once a new concept, object, phenomenon and the like appears. In this process, a name has undergone multiple attempts and word formation processes (Sager, 1990: p.63).

Translation Procedures: It refers to particular translation courses which are applicable to sentences and the smaller units of language. (1988). (p. 81). Newmark.

Word Formation Processes: It speaks of the continuous development of new terms and new

applications of old terms leading to language productivity in the way a language is evolved based on its user's requirements (Yule, 1988: p.52). There are different ways for word formation to enter lexicon.

Learning Assessment and Measurement

Implicit Cognitive Vulnerability

Caroline M. Crawford

University of Houston – Clear Lake, US

INTRODUCTION

Implicit Cognitive Vulnerability is a theoretical construct, a concept that engages in an understanding revolving around how a person understands information, shifts information from short-term memory into long-term memory access, and the vulnerability within the learner's cognitive processes that support or abandon the learner's ability to conceptualize the new information within prior learned information. Vygotsky (1933/1966, 1935, 1981) referred to this as the conceptual framework of understanding, fitting new information within the previously learned information. The intriguing shift in thought, referred to as Implicit Cognitive Vulnerability, suggests that the discomfort and tension surrounding learning new information and engaging with this information in new and different ways introduces a level of cognitive dissonance and conceptualized resistance to the person's re-envisioning information in new and different ways. This vulnerability, specifically cognitive vulnerability, is the inherent undergirding towards a rationalization revolving around understanding new information in new and different, creative ways as the information moves from short-term memory and into implicit, long-term conceptual frameworks of understanding. The objectives of the article is to frame an understanding of Implicit Cognitive Vulnerability as a developing learning theory that supports one's understanding of the instructional process. This includes the supportive development of a "comfortableness" within the instructional environment that supports the learner's cognitive efforts and developing understanding of prior information with new information, as well as the creativity involved in "thinking outside the box" within a safe and supportive environment.

DOI: 10.4018/978-1-5225-2255-3.ch447

BACKGROUND

Cognitive vulnerability within the realm of cognitive psychology has a focus upon states of emotional depression (Haeffel & Hames, 2014; Hanklin & Abramson, 2001; Matthews & MacLeod, 2005; McGinn, Nooner, Cohen & Leaberry, 2015). However, within the learning process, one might suggest that cognitive vulnerability is not so much a state of depression, as much as a state of cognitive dissonance wherein the learner is attempting to understand information in new and different ways, by not only framing the information within the previously developed knowledge base, or conceptual framework of understanding (Vygotsky, 1933/1966, 1935, 1981) as well as the learner's need for support within Maslow's Hierarchy of Needs (1943, 1954, 1962, 1968, 1964/1970a, 1970b) that frames a five stage model that frames the deficiency needs (physiological, safety, social, esteem) and growth need (self-actualization) as vitally important areas of impact upon a learner's motivational needs. One may suggest that the vulnerability inherent within the learning process engages Vygotsky's conceptual framework of understanding the specific subject matter that also includes the connectedness of the new information with previously understood information, with Maslow's Hierarchy of Needs that engages in the safety and esteem aspects of the community of learning (Klamma, Rohde & Stahl, 2005; Swan, 2002). This also supports Wittgenstein's (1961) work related to a learner's understanding of information within the realm of their own socially communicated and socially corrective understandings that frame learned information within a social context that may be perceived as the community of learning environment

as well as the larger community of practice that also includes the larger social realm of influence.

The importance of Implicit Cognitive Vulnerability within a community of learning is clearly articulated through an understanding of the deficiency needs as defined by Maslow (physiological, safety, social, esteem) that clearly embraces the impact of the social realm upon the learner that includes not only the instructor but also the collegial learners. This includes the vitally integral support of the community of learners as a safe, supportive area that embraces self-efficacy (Bandura, 1977, 1986, 1997) as a motivational effort, including the expectancy construct (Parsons & Goff, 1978), supporting Vroom's expectancy theory (1964) that, according to Holdford and Lovelace-Elmore (2001), Vroom supports an understanding that "intensity of work effort depends on the perception that an individual's effort will result in a desired outcome" (p. 8). This supports an understanding towards the self-actualization and creativity that are inherent not only towards Bloom's Cognitive Taxonomy (Bloom, 1956, 1984; Bloom, Englehart, Furst, Hill & Krathwohl, 1956; Bloom & Krathwohl, 1956; Krathwohl, Bloom & Masia, 1964). This also includes Anderson and Krathwohl's revised Taxonomy for the Digital Age (2001) focus upon higher order thinking skills achievements but also towards supporting the creativity inherent within higher order thinking skills that may be described as "out of the box" creative thinking in new and different ways that are inherently vulnerable arenas into which one may journey boldly.

MAIN FOCUS OF THE ARTICLE

The primary concerns revolving around the conception of Implicit Cognitive Vulnerability have to do with the impact of the instructional facilitator, the collegial learners, and the subject matter prior experience on the part of the learner. Each aspect within the instructional environment is integrally

important to the impact upon the learner's cognitive understanding and implicit memory retention and retrieval. Simplistically stated the triad of components, or constituents, within this instructional process are imperative towards supporting and engaging the learner's successes.

Instructional Facilitator

The instructional facilitator is the learning community mentor, wherein the tone of the learning community is set and the level of collegial support by all members within the instructional community is gauged. The instructional facilitator's style of instructional presentation of materials to the learners, the ways that the students engage with the information, and the levels of direct engagement with higher order thinking skills efforts is directly designated and supported by the instructional facilitator. As well, the level of collegiality and professionalism of the learners within the instructional environment is set up and supported by the instructional facilitator, towards being a supportive environment in which learners are indeed colleagues who support the engagement with the information while also engaging in either supportive or non-supportive "out of the box" nontraditional and creative thought processes. This understanding and engagement may more fully address using the information in new and different ways, that not only integrate the new knowledge within each learner's conceptual framework of understanding, as checked and corrected by the instructional facilitator as well as learner colleagues, but also more fully supports the integration of new information into each learner's implicit memory attainment. The "comfortableness" modeled by the instructional facilitator guides the learners towards a collegial engagement within the bound learning environment, wherein a sense of "comfortableness" and creative engagement with the subject matter and learner colleagues may develop into a sense of community engagement that supports the learner's

motivational and self-efficacy efforts as undergirded by belonging and engaging as an important member of the learning community.

Collegial Learners

The collegial learner is the second component of the triad. The leadership, guidance and mentorship of the instructional facilitator directly impacts the collegial learners, not only as singular learners but also within a collegial community of learners. The concept of Vroom's Expectancy Theory (1964) lives within a performance-reward correlation that supports the instructional facilitator's mentorship and expectations revolving around the learning community that is perceived and rewarded. Towards understanding the learning community expectations as set by the instructional facilitator, the learner colleagues develop an understanding as regards boundaries, communication and relational expectations, as well as levels of performance expectation that is set with not only the information learned but also the relational performance between learner colleagues. Expectations as regards supporting all members of a community are modeled and embraced by the instructional facilitator, with the expectation that the learner colleagues follow suite and engage in similar levels of quality engagement and expectation. The expectations revolving around perceived effort, perceived performance and collegial respect and support are integrally important towards supporting the instructional process that occurs within the learning community. The ability of the collegial learners to delve into cognitively vulnerable efforts, directly understood as being potentially uncomfortable and vulnerable new ways of thinking about the information being learned, is an inherent undergirding of the learning process that results in the learners engaging with the information towards the higher order thinking skills arena as designated by Bloom (1956, 1984; Bloom, Englehart, Furst, Hill & Krathwohl, 1956; Bloom & Krathwohl, 1956; Krathwohl, Bloom &

Masia, 1964) and Anderson and Krathwohl (2001); specifically, the learners are engaging with the information at the levels of analysis, synthesis, evaluation and creation of information in new and different ways. The level of cognitive vulnerability of the learners, to engage with co-learners and with the instructional facilitator within unclear, creative and vulnerable levels of understanding the information being learned, brings forward not only a cognitive dissonance but also a cognitive vulnerability within the learner's own sense of learner self and self-efficacy. The learner's desire to support a level of self-efficacy and learner self while engaging in cognitively vulnerable efforts will naturally develop a level of cognitive resistance, as engaging in each level of higher order thinking skills is uncomfortable and rationally difficult to achieve. The instructional facilitator supports the collegial learner's efforts within the community, supporting, correcting, coaching and rewarding each learner's efforts towards developing a stronger conceptual framework of understanding as regards the new information's integration into long-term memory, as well as the ability of each learner towards developing a comfortableness with the concept of sharing their own creativity and creative ideas with others in a cognitively vulnerable manner. The more fully the instructional facilitator supports the collegial learner's efforts towards working with the information in cognitively vulnerable manners, the more fully the learners will embrace the new information within their own schemas of understanding and implicit memory engagement.

Subject Matter

The subject matter is the final component of the triad. Different groups of learners bring forward different conceptual understandings as revolves around their own past experiences, their own prior knowledge base, and their own conceptual frameworks of understanding as regards the subject matter addressed within an instructional

environment. This understanding of the learner's background and levels of prior knowledge attainment as well as levels of engagement and expertise with the subject matter will guide the instructional facilitator's instructional design for the instructional experience. Meaning, if the learners within the community of learning are novices with the specific subject matter, then the learners will require a significantly different approach towards working with the knowledge and remembering it, to understanding the knowledge, and then the inherent application of the new knowledge; each of these aspects are considered lower order thinking skills within Bloom's (1956, 1984; Bloom, Englehart, Furst, Hill & Krathwohl, 1956; Bloom & Krathwohl, 1956; Krathwohl, Bloom & Masia, 1964) and Anderson and Krathwohl's (2001) cognitive taxonomies. The instructional facilitator must work with the learners towards ensuring that the subject matter is understood and have fully engaged with the knowledge at these lower levels of thinking skills in carefully orchestrated progression, so as to then more fully engage with the subject matter at higher orders of thinking and subject matter engagement. As the collegial learners progress through each level of subject matter understanding and engagement (as designated by Bloom's and Anderson and Krathwohl's work), the cognitive vulnerability of the learners is recognized as cognitive dissonance and cognitive vulnerability, as the learners strive towards overcoming a sense of cognitive resistance and achieves a higher level of subject matter understanding, engagement and the slow shift of information from short-term memory towards long term memory engagement and understanding. The subject matter is an integral aspect of the instructional process, specifically as regards the conception of Implicit Cognitive Vulnerability, as different information is appropriately learned in different manners by different groups of learners. To more simply state this, different information is learned by different learners in different ways.

SOLUTIONS AND RECOMMENDATIONS

An interesting discussion revolves around Implicit Cognitive Vulnerability and ways to deal with issues, controversies or problems associated with the concept of Implicit Cognitive Vulnerability. One instructional style does not meet the needs of every single learner, even if the subject matter is similar in presentation and prior knowledge attainment and understanding. Much of this may be the ways that different instructional facilitators present the subject matter to the learners; as well, much of this may be due to the community of learning that is developed and the trust that bonds the collegial learners within the instructional environment.

Instructional Facilitator

Again this discussion returns to the instructional facilitator, as the instructional design and presentation of the subject matter within an instructional environment is framed by the instructional facilitator's philosophical beliefs systems as regards the beliefs revolving around how people learn, why people learn, framing the information for the learners, as well as the level of community support and engagement necessary towards modeling a conceptual framework of understanding. This occurs through social discourse and communicative choices that engage with the subject matter being learned. The quality of instructional experience is framed by the instructional facilitator, although the subject matter and the community of learning's collegial learners also are integrally engaged in the instructional successes that support the concept of Implicit Cognitive Vulnerability. The instructional environment in which the learners engage with the information is initially framed and supported by the instructional facilitator, with decisions made as to the "comfortableness" and cognitive safety of the learners throughout their instructional experience. As well, the support

towards “thinking outside the box” in new and different ways can be reinforced and sustained by the instructional facilitator to different levels of being and different motivational and self-efficacy senses of belonging.

Reflective Practitioner

Solutions that embrace the concept of a reflective practitioner may be framed through Cruikshank’s (1987) Reflective Teaching Model that fully engages the instructional facilitator in analyzing their own instructional practices and peccadillos. This analysis more fully supports the realization of an instructional facilitator’s unique ways of “being” and of “teacher presence” that also suggests one’s ability to engage in conflict resolution within a professional and mutually inclusive and respectful manner. The reflective understandings that are derived from an instructional facilitator’s reflective practices and ability to critically analyze one’s own strengths, weaknesses and areas of necessary improvement suggest that not only is the instructional facilitator open and cognitively vulnerable in one’s own manner of being, but also offers a more self-serving recognition that the instructional facilitator is more attuned to the needs of the collegial learners and a stronger mentorship understanding may engage a stronger sense of engagement. This stronger sense of engagement and respectful understanding of the needs of the collegial learners within the instructional community more fully supports the concept of Implicit Cognitive Vulnerability. Recognizing, supporting and engaging the developing self-efficacy of the learners associated with the subject matter, as well as within the learner’s own sense of ability, “comfortableness” and internalized sense of motivation within the instructional environment can be more fully realized through the reflective practitioner’s own sense of engagement and reflective understandings of the learner’s efforts associated with the subject matter, with the learning community, with the cognitive efforts towards not only “comfortableness” but also stretching one’s own

analytical abilities towards creativity that may be described as “thinking outside the box” in new and different ways that are recognized as safely occurring within a bound learning community.

FUTURE RESEARCH DIRECTIONS

Directions for future research are intriguing, as the concept of Implicit Cognitive Vulnerability as an understanding revolving around the learning processes and needs of learners is in its mere infancy. Recognition of the learner’s need for cognitive support throughout the instructionally relevant learning process is inherent, while recognition of the learner’s cognitive dissonance and cognitive vulnerability as an in-between aspect of concern as the learner progresses from the lower order thinking skill domains towards each successively higher cognitive taxonomy thinking skill domain (Anderson & Krathwohl, 2001; Bloom, 1956, 1984; Bloom, Englehart, Furst, Hill & Krathwohl, 1956; Bloom & Krathwohl, 1956; Krathwohl, Bloom & Masia, 1964) must be more fully understood and supported. More fully supporting the learner at these sensitive points of informational engagement and vulnerability will aid in successively lowering the potential levels of resistance in the learner’s cognitive efforts with the conceptual framework of understanding and implicit memory attainment that shifts a learner from novice subject matter understandings towards more experienced understandings revolving around the subject matter. The recognition that the community environment is integrally important is also vital towards the success of the learner, as the social aspects of the learning process directly impacts the learner’s successful attainment of the information.

A stronger understanding of the learner’s cognitive dissonance and cognitive vulnerability, specifically as it impacts the learner’s ability to understand and work with the subject matter informational attainment must be more fully addressed. The social engagement and vulnerable

cognitive points throughout the learning process must also be more fully understood. These are integrally important aspects to consider, within the Digital Age impact of not only traditional instructional environments and the influence of the instructional facilitator within this environment, but just as vital are the instructional environments of blended learning, online learning and mobile learning. The dichotomy that currently exists within the instructional environments must be addressed through future research opportunities.

CONCLUSION

The impact of the instructional facilitator, the subject matter and the collegial learner environmental community engage in impacting the learner's Implicit Cognitive Vulnerability. The viability of this theory cannot be more strongly emphasized, as the impact of the instructional environment's framing and support structure embraces a learning community that is also viable towards directly impacting the learner's successful attainment of the information desired.

KEY TERMS AND DEFINITIONS

Cognition: Cognition is a term that focuses upon the thought processes of a person. Within this discussion, the term revolves around the mental processes of persons involved in the instructional process.

Cognitive Vulnerability: The term is primarily implemented within psychology as suggesting a person's depressive state. Within this discussion, the term does not suggest a level of mental depression. Instead, this term focuses upon a sense of dissonance, meaning discord or conflict, within a person's mental processes while learning new information but more directly this term focuses upon the learner's efforts towards using information in new and different ways of understanding.

Collegial Learner: This term is offered as a label for all learners within an instructional environment. This term is implemented with the desire to reflect an instructional community environment wherein the students come together and support each other's instructional understanding as well as supporting each other's knowledge attainment while using the knowledge in new and different ways of understanding.

Community of Learners: This term is an overarching understanding of the group of students, also including the instructional facilitator, who come together with the intention to learn information while also supporting the larger group's instructional understandings and efforts. This term reflects a philosophical understanding, that learning is not a singular activity but, instead, is a socially supported effort.

Conceptual Framework of Understanding: This term was coined by Vygotsky (1933/1966, 1935, 1981) and means that all information is remembered by a person in a mixed understanding with other information. No learned information stands alone; instead, the information is linked within each person's understanding with other prior knowledge, whether learned or experienced information. This occurs in a social context wherein the person learning the information, or

re-learning prior information, is making connections of understanding between all prior knowledge points that connect with the current information under study. The checking of understanding occurs in a social context, with re-learning and re-connecting prior knowledge information occurring as is appropriate.

Instructional Facilitator: This term reflects the role of the teacher within any instructional environment. The reason for the term is the understanding that the teacher is not only a “sage on the stage” but is also a mentor, a coach, and a Socratic questioner as is necessary and appropriate towards supporting the learning efforts within the instructional processes. Facilitating each learner’s efforts is the role of the teacher.

Reflective Practitioner: This term focuses upon the professionalism of the teacher, suggesting that the continuous analysis of the teacher’s strengths, weaknesses and areas of further development are necessary and appropriate towards

recognizing the ever evolving understanding of the profession.

Subject Matter: This term reflects the information that is meant to be taught by the teacher, and learned by the students.

Vulnerability: This term describes the cognitive understanding of the instructional process, wherein the student engages in differentiated understanding and efforts associated with the subject matter being learned. The student’s comfortableness with the information, the student’s comfortableness and engagement within the instructional environment (including the level of trust that the student feels towards the teacher and the other students) can further enhance each student’s ability to openly articulate creative thoughts and ideas, feeling a sense of safety that the student will not be derided for potentially incorrect understandings or “thinking outside the box” creativity that may be unusual understandings and ideas implemented with the subject matter under study.

INTRODUCTION

Reinforcement of the technology-enhanced education transformed education and training into a data-intensive domain. The software systems implemented in the education institutions (e.g. student information systems, library systems, university timetabling systems, attendance monitoring systems, lecture capture/media streaming systems, ePortfolios, assessment systems, curriculum maps, personal tutor system, student engagement system, social learning platforms etc.) made available large amounts of data related to the learning/teaching processes, etc. Educational data reflects not only the students' background, but also the students' performance. Each action carried out by students in different educational activities is stored and can be analyzed. The amount of data stored in different systems is impressive, for this reason the big data related technologies (Hadoop, Cloud etc.) are increasingly present in the IT infrastructure of education institutions.

As in many other data-intensive domains, the interest for data analysis through various business intelligence solutions is growing in the education domain. Improvement of educational activities by continuous analysis of collected data is a common practice in many educational institutions. More and more software tools are used for: modeling students' learning behavior (in order to understand

how students are engaged into online activities and how their performance can be increased), identification and evaluation of students' performance factors (in order to predict performance/lack of performance), prediction of dropout and retention at very early stages, monitoring students' progress and comparing them to their peers, in order to increase professors' awareness during learning activities, personalizing the educational processes mainly by choosing specific learning content, or improving feedback and assessment services, in order to increase students' awareness about the progress and their contribution in learning activities. By applying different business analytics methods, all these applications were associated to a new emerging field of technology-enhanced education, named learning analytics.

Learning analytics (LA) contributes to the quality assurance and improvement in education institutions (Sclater, Peasgood, & Mullan, 2016). The students and teachers could improve their learning and teaching processes. Also, the administrators could use LA as diagnostic tool for identifying issues and for improving the modules and degree programmes design. LA can lead to the development of new quality metrics and standards in the education domain and to demonstrate the compliance of education institutions to them. Some of the main positive effects of LA are the boosting of retention rates (LA allows to identify

students at risk and efficiently act with advices and support at very earlier stages) and the adoption of the adaptive learning, through the personalization of educational experiences. Students have the opportunity to take control over their own learning, having the possibility to monitor their current performance in real-time and help them to make informed choices about what to study. LA survey results (Newland, Martin, & Ringan, 2015; Sclater et al., 2016) show a clear adherence of stakeholders to LA adoption initiatives.

Although there is a growing interest for LA, the progress in the implementation of LA applications is still inconclusive, mainly due to the reduced maturity of technology-enhanced education and the lack of specific LA expertise. According to the HeLF survey (Newland et al., 2015), nearly half of UK higher education institutions have not yet implemented LA and about a third are working for LA implementation. The most common applications are the students' retention and the learning process enhancement. Responsibility for LA implementation is undertaken by different departments (Quality, Planning, Registry, IT Services, eLearning, Academic Development, Learning Services, Academic etc.). Three quarters of senior management have limited levels of understanding of the possible LA benefits and outcomes.

Another study undertook in the Danube Region of Europe (Bodea et al., 2016; Dascalu, Bodea, Stancu & Purnus, 2016) reveals that only 55.9% of the professors use a learning management system (LMS) in class, especially for content sharing and communication via forums and chats and social networks for keeping the connection with their students. Most of them (81.3%) consider the development of a social learning platform with LA functionalities as very relevant initiative for Danube Region. Regarding the students, most of those who participated to the survey use LMS in classes (75.2%), in order to share content (82.5%), to be assessed (48.5%) and collaborate (40.2%). Most students consider forums, webinars and

chats to foster online collaboration. The majority of students (88%) consider the development of a social learning platform to be relevant or very relevant for the Danube Region and more than half (58.6%) see advanced learning analytics as a mandatory feature of such a platform.

The article starts by defining LA, with relevant views on the literature. A discussion about the relationships between LA, educational data mining and academic analytics is included in the background section of the article. In the main section of the article, the learning analytics, as an emerging trend in the educational systems is described, by discussing the main issues, controversies, problems on this topic. The final part of the article presents the future research directions and the conclusion.

BACKGROUND

There are various definitions of Learning Analytics (van Harmelen & Workman, 2012; Siemens, 2010; Cooper, 2012; Ferguson et al., 2015). According to the definition proposed by the Society for Learning Analytics Research (SoLAR), LA involves “measurement, collection, analysis and reporting of data about students and learning contexts in order to understand and optimize learning and the environments in which it takes place” (van Harmelen et al., 2012). LA means “intelligent use of data produced by students and analysis of existing patterns in the data, finding information and social connections to predict and advice on learning paths” (Siemens, 2010). At the same time, the cultural values of contemporary society have changed: according to Harvard Business Review, the online learning environments are seen as the great educational revolution (Tamny, 2013). LA aims to explain the impact of cultural changes on the learning process and to optimize it accordingly. LA is, therefore, more than metrics; it is a process (Bischel, 2012). LA represents the usage of analytic techniques on educational data,

being often associated with business intelligence, data mining, web analytics, academic analytics, action analytics and predictive analytics.

According to Romero and Ventura (2013), educational data mining (EDM) means “developing, researching, and applying computerized methods to detect patterns in large collections of educational data that would otherwise be hard or impossible to analyze due to the enormous volume of data within which they exist”. Papamitsiou and Economides (2014) examined the literature on experimental case studies on EDM and LA which were conducted in 2008-2013. They conclude that EDM and LA represent two areas oriented towards the inclusion and exploration of big data capabilities in education, by using analytic techniques to evaluate rich data sources, identify patterns within the data and exploit these patterns in decision making. Associated to these two domains there is an ecosystem of methods and techniques for data gathering, processing and reporting, in order to inform and empower learners, teachers and educational organizations about performance and goal achievement, and facilitate decision making accordingly. Chatti, Dyckhoff, Schroeder and Thüs (2012) also consider EDM and LA as being two separate communities which share similar goals and focus but having different origins, techniques and areas of applications. While the LA adopts a holistic framework, seeking to understand the educational system as a whole, EDM applies a reductionist approach by seeking for individual patterns of specific components of the educational systems. Analyzing the differences, similarities and evolution of EDM and LA, Linan and Perez (2015) consider the application process as being the main difference between EDM and LA, while Siemens and Baker (2012) identify the following distinctions between EDM and LA: aims (EDM is interested in the data-driven discovery, while LA is focused on human learning process), the approach (EDM reduces systems to components, while LA analyzes the whole system), the roots (EDM is rooted on student modeling, while LA is related to semantic technologies) and applied

methods (EDM employs methods of classification, clustering and associations mining, while LA focuses on concept analysis, social network analysis, sentiment analysis and discourse analysis). Bienkowski, Feng and Means (2012) consider that LA is a multidisciplinary domain, being connected not only with education, computer science and statistics, as it is the case of EDM, but also with sociology, psychology, linguistics and learning sciences. In this regards, LA is different from EDM being more learning science-driven than data-driven. This make that LA uses different types of data compared to EDM when the students and learning contexts are monitored and analyzed, for example: preferences, affect observations, forum and discussion posts. These disciplinary influences make EDM to be more IT oriented, unlike LA that is more learning oriented.

Academic Analytics (AA) represents the usage of analytical techniques to support decision making in education institutions. Instead of learning and teaching processes, AA is focused on the business of education institutions, with marketing and administrative orientation (Ferguson, 2012; Siemens & Long, 2011). The main target group for AA are the managers/executives and not the students and teachers.

LEARNING ANALYTICS DRIVERS AND BARRIERS

LA has a rapid evolution, due to several opportunities which exist. But, there are also many barriers limiting the LA expansion in education and training.

An important driver of LA evolution is the financial pressure facing many educational institutions in our days. The budget constraints create strong demands for expenses rationalization and enhancing the efficiency and effectiveness of all education activities. Better retention rates, an increased satisfaction of the students and other stakeholders and, finally, higher enrolment figures lead to the improvement of the economic situation

of educational institutions. LA allows teachers and administrators to early predict students' dropout and to identify factors for increasing the retention. Having this information, teachers can increase the students' engagement in learning activities and consequently increase their satisfaction and retention.

The demands of students and other stakeholders are also increased. The students, as consumers which pay fees for education services expect more personalized and motivating learning experiences and better academic performance. Personalized interventions such as better recommendations/advice or formative assessments increase the motivation of students for learning (Bodea, Dascalu & Lipai, 2012). LA contributes in producing meaningful feedback and a better pedagogical support for the students. LA allows identification and evaluation of various factors as indicators of performance, for prediction purposes but also for deciding actions to increase students' performance. Some analytics are used by teachers to monitor the performance of students, being able to adapt their teaching strategy during the course delivery and make changes in content and processes.

The integration of different systems implemented in education institutions into virtual learning systems/platforms (VLEs) or learning management systems (LMSs) represents an important LA driver. The amount of data available on these platforms is impressive, considering the fact that not only the students' personal and performance data are stored, but also educational resources (e-books, videos and audios when delivered lectures are captured but also multi-media educational resources, serious games, scenarios, simulators). Considering this huge amount of data, the big data related technologies (Hadoop, Cloud) are increasingly present in the educational infrastructure. The existence of VLEs/LMSs, making available large amount of data represents a good premise for adopting LA. The integration of different data sources into one single "learning warehouse" allows analytics functions to be added to VLEs/LMSs.

Massive, open, online courses (known as MOOCs) paradigm represents a flexible online courses delivery model, allowing the participants to choose when and where to study and the level of involvement). MOOCs were considered as a 'learning revolution', mainly because provide a global access (no entry requirements or fees) and participation at good education and training (Katsarova, 2015). MOOCs are mainly developed by private companies in partnership with universities or individuals, on open-source web platforms. *Coursera* (developed by Stanford University) and *edX* (MIT and Harvard University) are very well-known examples of MOOCs. MOOCs are usually characterized by a large number of enrolled students with different backgrounds, learning experience, education levels, language skills, objectives and needs, a high dropout rates and different patterns of participation (Clow, 2013). In this context, there is an important potential for LA. Available data from thousands of students can be used for designing new courses and new training processes for new student generations. The concept of adaptive MOOCs has also emerged, based on the educational personalization achieved through analytics in MOOCs environments. Sonwalkar (2013) presents an aMOOC platform, developed by using the Amazon Web Services' cloud architecture. It is expected that the research interest in aMOOCs to increase in the next years.

Social networks became important facilitators in information exchange, engagement and overall connection between peers. The social learning is based on the usage of social networks in e-learning activities. The strengths of social learning are: it is fully accessible and affordable, it boosts collaboration and active learning and it enhances learner engagement. The weaknesses of social learning are the following: it is distracting and not secure as a learning management system, it limits the control one may have over the learning content and it cannot provide feedback on performance (Pappas, 2015). A promising direction of LA research is the *social learning analytics*. The efforts in this direction are more exploratory than explanatory. Shum and Ferguson (2012) identify several sub-

domains of social LA: social network analysis to see the connection between students, educational resources and ideas; discourse analysis, to see how to build knowledge; content analysis of actions taking place in the virtual environment; analysis of the student's mood, meaning what motivates him to learn and context analysis, supported in particular by mobile technologies, which provide information about the learning habits, for example when and where learning takes place.

The availability of different LA tools and the experience already gained in other business domains in applying analytics methods represents an important LA driver in order to explore better the student learning processes and to find efficient ways to improve them. The HeLF survey (Newland et al., 2015) finds that institutions applied or consider a variety of different LA solutions, including their own in-house developments. Table 1 presents some examples of LA tools.

Table 1. LA tools examples

Learning Analytics Tools	Examples
LA extensions for LMS	LA extension for the Khan Academy platform (Ruipérez-Valiente, Muñoz-Merino, Leony & Kloos, 2015), for a better understanding of educational processes LA extension for virtual learning worlds developed in Opensim (Fernández-Gallego, Lama, Vidal & Mucientes, 2013)
"Opportunistic" learning tools	Active Campus – an application that can connect students and resources, through alerts about friends, colleagues or potential educational events in one's proximity (Griswold et al., 2004)
Context analysis tools	MOBilearn (Syvanen, Beale, Sharples & Ahonen, 2005)
LA tools for virtual learning environments	GRAPPLE Visualisation Infrastructure Service (GVIS) platform, which aggregates data about users working in different virtual learning environments and create their profiles (Mazzola & Mazza, 2010)
LA tools for mobile applications	LearnTracker, a mobile application that tracks the learning process of students (Tabuenca, Kalz, Drachsler & Specht, 2015).

There are not only opportunities but also barriers which affect the LA dynamics, such as:

- Lack of expertise, for a significant number of teachers and managers with regard to LA. In order to mitigate this problem, it is important to increase acceptance and develop a data-driven culture in educational environments (Romero et al., 2013).
- Barriers related to the ethics and personal privacy (Greller & Drachsler, 2012). Ethics must be taken into account in all stages, from data gathering to the interpretation of outputs and decision making, for instance, by avoiding statements that could lead to discriminatory treatments when working with gender, social status, race, home country, religious beliefs, ideology or disability. Similarly, issues related to the ownership of students' data, which differ from country to country, need to be considered.

LEARNING ANALYTICS METHODS AND AREAS OF APPLICATIONS

The main groups of learning analytics methods are the following:

- Reporting Analytics

These methods allow reporting on the past situations. Various types of reports can be generated, such as: reports for selected activities, students, items and periods of time; real-time reports, for ongoing activities; regular activity reports, regarding the students for selected students, a given period and courses/activities etc. Blackboards and Google Analytics also offers several types of reports. Data visualization methods, such as: heat maps, learning curves and Isax1s can be also included in this group, assisting the distillation of data for human judgment.

- Automated analytics, such as: clustering, factor analysis, social network analysis and domain structure discovery.

They provide models for end-users to understand and deal with the present challenges (for example: cognitive models of students, which represent their skills and declarative knowledge, students' learning behavior models or models of domain structure). Even if these results/models are not produced by predictive analytics, they can be used to make predictions.

- Predictive analytics, such as: classifiers, regressors, association rule mining, correlation mining, sequential pattern mining and latent knowledge estimation methods. All these methods create predictive models to deal with future challenges.

Table 2 presents the main actual areas of application for the learning analytics with relevant methods and examples. Baker and Yacef (2009) study the proportion of works reporting the usage of each method group, during the period 1995 – 2009. From 1995 until 2005, the most applied methods were the relationship mining methods (43%) and predictive ones (28%). Human judgment or exploratory data analysis (17%) and clustering

(15%) were also popular. In contrast, in 2008-2009, the importance of relationship mining decreased (9%), while predictive methods reached 1st place (42%, of papers from 2008 reported the usage of predictive methods). The usage of human judgment and clustering methods remained relatively constant (12% and 15%, respectively). The application of the item response theory, Bayesian nets and Markov decision processes increased (28%).

SOLUTIONS AND RECOMMENDATIONS

The future of LA relies on the technological progress but also how some organizational strategic issues are managed by educational institutions.

Technological developments in the field of LA platforms address the openness and the architectural modularity. Openness has a critical role in the LA future, meaning usage of open source LA software (such as Weka, Kettle, Pentaho, R or Python), alignment to open standards and APIs for LA (such as: Experience API (xAPI) or IMS Caliper/Sensor API), adherence to open models and open content/access. Openness with regards to ethics/privacy issues means transparency and building the trust of end-users. Open Academic Learning Analytics Initiative (OAAI) is one example of the

Table 2. Areas of application and examples

Main Areas of Application	Learning Analytics Methods	Examples
Increase (self-) reflection and (self-) awareness	Reporting and automated analytics	Baker, Corbett & Wagner (2006) Santos et al. (2012)
Creating real time alerts for stakeholders	Reporting and automated analytics	Baron, J. (2015).
Improve feedback and assessment services	Reporting, automated and predictive analytics	Barla et al. (2010)
Student modeling	Automated and predictive analytics	Jeong & Biswas (2008)
Recommendation of resources	Automated and predictive analytics	Antonenko, Toy & Niederhauser (2012) Romero and Ventura (2013)
Scientific inquiry in education	Automated and predictive analytics	Baker, Corbett & Wagner (2006) Ming & Ming (2012)
Prediction of performance	Predictive analytics	Yadav & Pal (2012)
Prediction of dropout and retention	Predictive analytics	Ueno (2004)

strategic relevance of openness in the evolution of LA platforms. The architecture modularity means that the critical functions (data collection, storage, analysis and action) have to be assured by distinct components/modules of the platform. Jisc's learning analytics architecture (Sclater et al., 2016) implements this modularity concept. At the heart of Jisc architecture is the learning analytics processor where predictive analytics are carried out, and lead to action coordinated by the alert and intervention system. Data visualizations are available in a series of dashboards. The student applications allow learners to compare their performance with others.

The organizational strategic issues related to LA are the following: the organizational Leadership, culture and competences, assuring access to the educational data, ethics and privacy.

FUTURE RESEARCH DIRECTIONS

The future research in LA should address the actual limitations of the LA solutions (Ferguson, 2012; Agudo-Peregrina, Iglesias-Pradas, Conde-González, & Hernández-García, 2014) which negatively affect the extension of LA. The main relevant limitations are the following:

- Lack of sufficient application of science education in the implementation of LA (which would have the following benefits: optimized planning of the learning process, effective implementation of the principles of teaching and increasing students' self-awareness).
- Poor operation of different datasets (both in terms of the origin and type- mobile data, biometric, emotional, and so on) and their combination; we should understand that the current trend is to use multiple virtual learning environments or learning manage-

ment systems such as Moodle or informal social networks, thus a meaningful analysis of learner's data should be done on the data collected from all the environments in which he/she is active.

- Focusing less on student data analysis (taking into account their profile, career goals, motivational factors, etc.) and more on grades and institutional needs, which is not a solid approach.
- Lack of a clear set of ethical rules, taking into account the ownership and management of data.
- Lack of consensus regarding data relevance (what data is really important to be measured, understood and used in subsequent modelling) as being other relevant limitation of the current LA solutions.

LA research already starts to shift from technological aspects towards an educational focus. Also, it is expected that more LA research will be done in social learning analytics.

CONCLUSION

LA is a promising emerging domain, with associated strengths, weaknesses, opportunities and threats. LA strengths include the huge volumes of available educational data, availability of powerful methods for data analysis and a growing learning theory. LA weaknesses are the potential misinterpretation of data, lack of the education systems integration and lack of expertise in implementing LA platforms. LA opportunities include the existence of open standards for increasing the compatibility across systems and achievements in business analytics in other domains. LA threats are mainly related to the ethical and data privacy issues.

KEY TERMS AND DEFINITIONS

Academic Analytics: Advanced data analysis for improving the performance of education organizations.

Educational Data Mining: Data analysis for detecting patterns in large collections of educational data.

Learning Analytics: Advanced data analysis for understanding and optimizing learning and teaching. It is an emerging field of technology-enhanced education.

Social Learning Analytics: Learning analytics applied in social learning.

Social Learning: The usage of social networks in e-learning activities.

Predicting Students Grades Using Artificial Neural Networks and Support Vector Machine

Muhammad Majid Sharif

National University of Sciences and Technology (NUST), Pakistan

INTRODUCTION

Education is not limited to just studying books, cramming notes and passing exams. There are a lot of other activities and habits that can affect your education. If we know what type of habits are having a bad impact on our children's studies we can try to eradicate these habits and we can replace the one's with better impact. In fact changing daily lifestyle can improve children's learning skills. In recent times, learning analytics is being used by faculty members in their courses to help students learn and improve. Everything considered, these analytics play important part for the prediction of students' performance and its improvement. The definition of Learning analytics is that, the measurement, collection, analysis and reporting of data about learners and their contexts, for purposes of understanding and optimizing learning and the environments in which it occurs (Long & Siemens, 2011). Learning analytics is used for improving student's performance, to predict it and for the purpose of retaining because with learning analytics faculty, institutions and students are able to make data-driven decisions about student's success and retention (Uhler & Hurn, 2013). A classroom has a variety of students with performances on a broad range. Some of these students show great care and perseverance and are self-motivated but there are also those that have difficulty studying and understanding. Teachers are there to guide students and to motivate them. But observing

each and everyone's learning attitudes all over the periods in the semester is a hard task. Different regular assessment methods have been used in previous studies such as e-learning logs, test marks and questionnaires to observe and assess students' learning behavior. Although, teacher's observation plays important role to increase students educational situation, they get only a few cases requiring to their needs, mostly due to their experience in the class. In this chapter our focus is on finding those skills that are having bad effect on learning environment and suggest them to the parents. We used various data mining methods to find the outcomes and also verified by our class labels that how well our algorithm works. Data mining methods and tools we used in this paper are introduced in this part by a sequence in which they were used.

In this chapter first we will discuss the introduction part in detail. After this we will explain in detail, the literature review of the chapter and also discuss some important topics which play key role in this chapter. After this we discuss the implementation and results part. And at the end we discuss the conclusion and future work section.

BACKGROUND

In educational environments, it is very important to predict student's performance. To amplify a students' performance is a long-term goal in all aca-

demographic institutions in their learning environment. Now a day, data mining technique 'Educational Data Mining' (EDM) is used on a large-scale to automatically analyze the student's performance and his behavioral data with learning environments. The use of text mining is a new trend in EDM that extends data mining on text data. A lot of experiments have been done in past couple of years in areas to predict students' academic performance. A couple of methods have also been applied in Machine learning area to obtain useful/important data and for the prediction of future data trends.

Now we want to discuss in details about the Educational Data Mining (EDM). According to the websites being used for the educational data mining, the educational data mining is an emerging field. In this field we use and developed different type of methods which are used to investigate the different data types, which we collect from the field of education, and in future that data is used for the prediction and understanding of students. Moreover different experts (Baker & Yasef, 2009; Romero et al., 2010) categorize the educational data mining work in different categories like visualization, regression, statistics, classification and clustering. Educational data mining is used for different purposes in different fields like learning performance, judge students, increase learning process, pilot students learning, give evaluation and learning recommendation of student learning behavior, judge learning elements, judge problems and abnormal learning situations, and gain broad understanding of education (Baker, 2009; Gorissen, Bruggen & Jochems, 2012). Some Literature related to the educational data mining is given below. Gorissen and their group used the educational data mining technique and analyzed the student interaction with the record learning (Gorissen, Bruggen & Jochems, 2012). The lecture capture system is used for data and they combine and used that data with the survey data. They found variations and similarities between the actual data and students reports. The proposed data for the students have a bigger chance of qualifying the

exam. At the end they get a result and say that the difference between the actual data and the verbal report, the analysis will no longer depend on verbal report. Jovanovica and his team applied and tested the classification models which were used for the predicting the performance of students. And also applied the models related to clustering for the categorization of students on the basis of their cognitive styles in e-learning environment (Jovanovica et al., 2012). They prove and suggest that the model related to classification is very helpful and useful for students, teachers and business peoples.

Parack also used different algorithms related to data mining for profiling students on the basis of academic results and records like attendance, exam marks, practical exam and team work score etc and cluster them with the help of K-mean method (Parack, Zahid, & Merchant, 2012). They also found that the data mining is very helpful and important to explore and detect the important data relate to the profiling students.

Wu He also explained a technique which he used to exploit huge students data like chat messages and online questions and that data collected automatically with the help of system, that system is called live video streaming system (He, 2013). The results of text mining and data, acknowledge interesting patterns in the interaction of students and teachers. At the result the students related to health and education asked more questions as compared to the science and engineering students. Two courses related to education also have positive correlation between the final grades of students and number of questions.

Now we discuss the text mining and its role and importance. Text mining is the extracting and finding the important or useful data, directions, models, patterns, trends from the unordered text like HTML file, emails, text document etc. Different applications of text mining are summarization of text, analysis of links, extraction of information and data, clustering (Ananiadou, 2008). The text mining is also used for the extraction, integration, identification, and managing the data related to

the education and research. Text mining is an automated technique (Abdousa, 2010). Now a days, there are some knowledge related to text mining that emphasizes how we use this method for the purpose of test learning data. Tane and their group used the text mining methods and clustered data related to the learning according to the similarities and titles (Tane, Schmitz, & Stumme, 2004). Hung also used the clustering method to test the visualized patterns and e-learning literature (2012). Goda also presented a model related to the prediction of grades on the basis of comments of students. This method used the PCN technique. The result of this experiment shows that the students get lower PCN scores, then the prediction performance of the student grades becomes lower (Goda et al., 2013). Sorour also proposed a method which is used for the prediction of student's grades and this model is based on c-comments information (Sorour, Mine, Goda, & Hirokawa, 2014). They enforced K-mean method and LSA method on two class information/data and then get the outcomes of the applied methods by finding accuracy of grades.

C-comments are also used for the prediction of student's grades (Goda et al., 2013). C-comments shows the performance and understanding of the subject duration of the class and time of the class. Some examples of C-comments are given below

I fully understood the subject and feel courage to make different functions. I did not complete the entire exercise because I could not learn the methods and time was out.

The data collected related to comments in different classes and number of students is 123. They read Goda's course and they studied 15 lessons. In this experiment we collect comments from students from lesson 7 to lesson 15. The subject of lessons are programming related to C language. Some students are not present there for they did not provide the feedback or comments.

Five grade categories are used for the prediction of a student's grades from their comments to classify their marks. The process was done by having average marks of a student's report assigned 3 times and their attendance rate. The correspondence between grades of a student and the marks of a student are shown in Table 1 that is an output of their tests. For example, there are 40 in grade A with marks between 89 and 80.

Artificial Neural Networks

Artificial Neural Networks are basically inspired by biological neural networks (Jain et al., 1996), this model of neural networks was first proposed in 1943 by Warren McCulloch and Walter Pitts, and they presented their first idea based on math-

Table 1. Students grades and the range of marks

	S	A	B	C	D

emational algorithm specially using threshold logic (McCulloch & Pitts, 1943). Artificial Neural Networks were not very popular at first because of too much computational power was required to process them and they used to take long time to develop a model. But as the time passed availability of computational power became easy but in 1969 Marvin Minsky published two major issues in artificial neural networks one of them was the use of single layer (Minsky & Seymour, 1969). But the concept of Multiple Layers in deep learning that came in late 2000s renewed the scientist's interest in artificial neural networks (Hinton, 2007). The model of Artificial Neural Network is shown in Figure 1.

Artificial Neural Networks usually consist of a large number of inputs and some hidden layers usually one to two, though more hidden layers are possible but that makes the model too complex to implement. Connections between inputs, hidden layers and outputs are usually weighted and these weights are the real part of Artificial Neural Networks we are interested in. Whenever we want to devise a new model we give new inputs at the start, known as training set, then we set a learning rate and start the algorithm. Back Propagation (explained later) method starts adjusting the weights, once these weights become constant up

to the fraction we chose, this model is ready. Now if we want to predict a new value we just give new inputs and use our devised model's weights and the outputs at the end are our new predicted values. Every new model depends only on the weights between these connections. Our goal is to modify the weights between the connections so that they represent the model we want to prepare for our purpose. ANN layers model is shown in Figure 2.

Back Propagation is the method that is usually used to modify the weights or we can say to learn the weights that represents our model. Back Propagation is very slow indeed it can take thousands of iterations to learn the weights. But once the weights are learned and the model is built it makes all the work very easily and the predictions or classification is very fast after that (Werbos, 1974). So we don't care how much time it takes to learn the weights as long as its outputs are correct, which means error rate is very low.

Latent Semantic Analysis

This is also one of the famous neural language processing techniques that is widely being used to find relationship between the words. It works on the fact that if words are similar in meaning it means they can be correlated (Landauer et al.,

Figure 1. Artificial neural network model

Figure 2. ANN layers model

1998). Latent Semantic Analysis usually works in the form of matrix in which element (i, j) describes the occurrence of term i in document j (this can be, for example, the frequency). X Will look like this (Dougherty, Natow & Vega, 2012).

d_j
↓

$$t_i^T \rightarrow \begin{bmatrix} x_{1,1} & \dots & x_{1,n} \\ \vdots & \ddots & \vdots \\ x_{m,1} & \dots & x_{m,n} \end{bmatrix}$$

In our case instead of using different documents we have to use different aspects coming from same data source.

Support Vector Machines

Support Vector Machines are based on supervised learning model, which means some of our data which we intend to use as our training set (Hearst et al., 1998). Support vector machines are used for categorization of hypertext and text and also categorize their applications. Support vector machines are also used for transductive settings and also for standard inductive settings. Support vector

machines is also used for labeling the training data. We can also use the Support vector machines for image classification. Support vector machines are best from other search schemes because the accuracy of the Support vector machines are higher than the other methods and they provide the best and fast results compare to the others machines or methods Support vector machine is also useful in medical field. In support vector machine we basically find support vectors, that are tuples from the original data, to define a hyper plane that classifies our data in two portions (In our case, is this habit good or bad for child). Support Vector Machines model is shown in Figure 3.

We want to maximize the margin between two dotted lines and the middle one solid line is the hyper line, in case of multidimensional data it's a hyper plane, is the one that classifies our data. Finding this hyper plane can be very tricky sometimes and also requires a lot of computations. To reduce the computations we use different kernel tricks (Tang, Guo, & Jinghuai, 2009), like one of them is shown in the Figure 4 below.

IMPLEMENTATION

In this section we discuss the methodology to predict the performance of student. We use Latent Semantic Analysis (Landauer, Foltz, &

Figure 3. Support vector machine model

Figure 4. Gaussian Kernel model

Laham, 1998) technique for prediction of student performance. In our work first we analyze our data and then we use) Latent Semantic Analysis method to predict the results of student and in the end we use Artificial Neural Networks model for classification. Our implementation needs the following steps.

1. First we collect the data related to the students like his remarks after the lecture, which includes: Level of interest, level of understandability, level of difficulty, practical knowledge. Teacher's remarks about student's participation, which includes: Behavior, social skills, communication, reading writing.
2. In the second phase we build a data set from the student remarks and give a fine shape to this data set. So in this part we separate all the parts of speech and find the occurrence of the work in the remarks or comments. After this we still need data cleaning as there can be a lot of empty occurrences or typing errors that prevents this data to fall into any category and now apply different methods like entropy to equalize or balance the frequencies occurrences. This data cleaning step is also known as preprocessing.
3. Now we apply the Latent Semantic Analysis model to find the relationship between the different words and analyze the words.

Further details of this step are discussed in later part of the paper.

4. When we get the results after applying the Latent Semantic Analysis model then we use the Artificial Neural Networks model for the classification of words or comments. This is also called the training phase.
5. In this phase we find the accuracy of the model / classifier. This phase is called testing phase. Flow of work model is shown in Figure 5.

For testing and finding accuracy of the model we use the cross validation method and we select K-folds for cross validation (Kohavi, 1995). For example we select 10 folds the then we select 9 for training data and the remaining 1 fold for test data, selection of data in each fold can also effect the output of our model. So while selecting data we consider two type of selections.

1. Random selection of data for every fold, which is naïve and enhances the chances of error, so it is not appreciated.
2. Supervised selection of data, in this method we distribute the data on basis of its type so that every fold of data has all types of data available in it. It is called well distributed data and can be handful to get better results, we use this type of distribution.

Figure 5. Work flow of model

Now let's see how our method works. According to the method first of all we find the similarities between the data. For this we analyze the data and we find this data contains different verbs, objects, nouns etc. Now in next step we create a vector model of these words. Vector model is actually the matrix which contains the words and their frequencies or weights. When we build the matrix then we normalize or balance the weights in the matrix. For this we use the global frequency or weight. The formula used to find the global weigh is

$$g_i = 1 + \sum_{j=1}^n (p_{ij} \log(p_{ij})) / \log(n)$$

g_i In the formula is basically an overall weight found from the whole set of remarks for this model. Whereas p_{ij} is the number of occurrences of word 'i' in a remark 'j' and 'n' is the total number of remarks used to devise the model. Flow diagram for finding similarities between the data is shown in Figure 6.

Latent Semantic Analysis is a powerful technique which is used to represent the language. This technique is basically representation of our English language and grammar data in the form of mathematics (Dearwester et al., 1990). There are three levels or steps of Latent Semantic Analysis,* the first is to simulate the natural language and find the frequency of every single word in the data, then decompose the data and build the matrix and show the words in the matrix along with their weights, and the last step is that the data is shown in the matrix in the form of a vec-

tor Latent Dirichlet Allocation work with the help of decomposition of a single value (Horn & Axel, 2003). For Latent Dirichlet Allocation we use the given formula $A = USV^T$. Latent Semantic Analysis; is used for the new data or comment and the formula for Latent Semantic Analysis is $q = q^T U_K S_{k-1}$.

Now when the data is divided and the method is applied on this data then we build different categories of the data and we give names to those clusters like cluster 1, cluster 2 and so on. Then we store the data in different clusters with the help of K-Mean clustering method. When the Latent Semantic Analysis is applied on the data then we perform this clustering method. We build the clusters according to the comments like we say that 62 % of one type of data lies in cluster 1 and 43 % * of data lies in cluster 2 and so on. According to our experiment we say that we have 5 grades like A + , A , B + , B and C + . Now 62 % of data in cluster 1 is of one type let's say A+ and 43 % of data in cluster 2 is A+, this is just a supposition as in our case every time different data comes in and percentage can change according to our data.

Every cluster has its own center which is called centroid (Jain, Murty & Flynn, 1999). Now we calculate the distance of each comment with the all cluster centers also known as centroid and the comment is placed in the cluster who's centroid has the least distance from the notation of this comment and this process is continued until all the comments are finished (Jain, Murty & Flynn, 1999). When the construction of clustering* phase is done then we perform the k-fold cross validation process.

Figure 6. Model of work flow

Now we have to calculate the prediction for the new item or comment. When a new comment occurs we have to decide in which cluster we should store this comment. For this purpose we use the measurement of similarity* method (Resnik, 1995). The formula used for finding similarity is

$$\text{Similarity} = \frac{S_{new} * S_k}{\|S_{new}\| * \|S_k\|} = \frac{S_{new} * S_k}{\sqrt{\sum_{i=1}^k S_{new}^2} * \sqrt{\sum_{i=1}^k S_k^2}}$$

In this formula S_{new} is the new item and S_k is the number of items in the cluster. Now we select the * Support Vector Machines to classify our data. The given diagram shows the details for the Support Vector Machines that how Support Vector Machines work in our method. When we collect the data and all the results are found then we give these results as an input to the Support Vector Machines which contains the pervious academic performance, personality information and biographical data of the student, these three categories are assigned to the Support vector machine as an input. The output of this Support Vector Machine that we designed also contains three sections behaviors, abilities of language and future academic performance. The detail Figure 7 is given below.

Date of birth and *gender are the example of bibliographical data. Past academic records means

that the students*grades or result of previous exam. Output results contains the future academics performance which means that the grades or marks of student in future subject like math, data mining etc. behavior tells us the abilities of the student like the student have leadership quality etc. for further explanation gender means that female or male, order of birth means that among the brothers and sisters the student order of birth. Support Vector Machine method was used to solve this problem which gets the input features or data and finds the correlation between different features and provide the final result related to the target results. The flow of the operations is show in the given diagram. First we collect the data then in second step we perform preprocessing on that data it means that we clean our data and remove all the noise from the data and we set the data for future processing. Now we select some data for training and select some data for testing. The flow of process is show in the Figure 8.

At the end we use the Artificial Neural Networks for the prediction and classification or selection of data it means that when the Latent Semantic Analysis operations are finished then we use three level perceptron for the calculation for student grads and performance. We create a perceptron for every input. The first layer shows the input layer, each input to the Artificial Neural Networks is the result of Latent Semantic Analysis. The middle layer is called hidden layer which contain a lot of neurons. The third layer

Figure 7. SVM Presiction model

Figure 8. Experiment procedure

is called output layer which gives us the results. In the diagram we get the 5 output results which go to its own neuron and each neuron is called the grade of student. Like grade S to grade C. Artificial Neural Networks with different Layers and outputs are shown in the Figure 9.

The back propagation plays a very important role in the Artificial Neural Networks because it updates the weights with the help of gradient descent. In Artificial Neural Networks we use the learning rate which is used to adjust or decrease the error and also the weights of the paths. In our case learning rate was kept low to get better results

so it is comparatively a slower method but gives us more accurate results. We perform the operations again and again until the error become minimized.

FUTURE RESEARCH DIRECTIONS

In future a greater set of remarks can be used to find a better model. We are also planning to use Dynamic Programming, another very popular algorithm, to predict the grades and analyze the impact of different habits of student on his final grades.

Figure 9. ANN with different layers and outputs

CONCLUSION

Latent Semantic Analysis when combined with Support Vector Machine found to be very useful. Overall we found that after matching our predicted values with the labeled data our prediction model gives very accurate results with quite an improvement over the previously used model. We deduced that, because of Support Vector Machines we are getting better results but we used Artificial Neural Network system with slow learning rate, its performance was better but overall speed of the whole learning process was slow so still there is a room for improvement especially in the process of learning speed.

KEY TERMS AND DEFINITIONS

ANN: ANN stands for Artificial Neural Network. Artificial Neural Networks usually consist of a large number of inputs and some hidden layers usually one to two. Connections between inputs, hidden layers and outputs are usually weighted and these weights are the real part of Artificial Neural Networks.

EDM: EDM stands for Educational Data Mining. The educational data mining is an emerging field. In this field we use and developed different type of methods which are used to investigate the different data types.

LSA: LSA stands for Latent Semantic Analysis which is famous neural language processing techniques that is widely being used to find relationship between the words. It works on the fact that if words are similar in meaning it means they can be correlated.

SVM: SVM stands for Support Vector Machines which is supervised learning model, which means some of our data which we intend to use as our training set. Support vector machines are used for categorization of hypertext and text and also categorize their applications. Support vector machines are also used for transductive settings and also for standard inductive settings.

The Relationship Between Online Formative Assessment and State Test Scores Using Multilevel Modeling

INTRODUCTION

The main goal of the current study was to examine the relationship between online formative assessments (FAs) and summative, yearly state proficiency test scores. Specifically, the relationship between one online formative assessment (FA) program in reading, known as the Diagnostic Online Reading Assessment (DORA), and state test scores in reading (i.e., the Colorado Student Assessment Program [CSAP]) was examined in four cohorts across elementary, middle, and high school in beginning in the 2004/2005 academic year and ending in 2009/2010. This investigation used Hierarchical Linear Growth Modeling (HLGM; i.e., Multilevel Modeling) to address the following research question: (1) What is the relationship between online formative assessment score growth and state test score growth?

Formal and informal FAs are one of many teaching methods that have been used to increase student performance on end-of-course, academic year, and other high-stakes achievement tests for decades and has a large research base to support

these practices (e.g., Black & Wiliam, 1998a). Additionally, summative assessment data (e.g., yearly state proficiency tests) are continually used as indicators of school and district performance for policymakers and the public. However, these summative data are of little use in the day-to-day activities of teachers in diagnosing student learning progress and modifying teaching strategies, as is done in the FA process (e.g., Black, 2015). Because this collection of abstract theories and research methods have transitioned into actual teaching practices, it is important to build the literature surrounding technology-based methods as teachers continue to use FA in the classroom.

The purposes in conducting this study include the following: (1) To support the burgeoning literature outlining the role of technology in general in teaching and learning, and (2) To bolster support for federal initiatives and administrative demands for more efficient ways to meet state standards. As technology-based assessment is gradually used to support and/or replace traditional forms of evaluation, the need to examine the extent to which these methods are educationally sound is

in high demand. Overall, information presented in this study can provide practical implications to district-wide implementation of supplemental reading instruction in an online environment.

BACKGROUND

E-learning (i.e., learning that is facilitated by electronic technologies) is referred to as part of the equipment of 21st Century scholarship (Buzzetto-More & Guy, 2006). However, e-learning is only half of the equation as government mandates have required schools to use data to inform decision making. The use of data has necessitated the development of improved information technology and access to computers and high-speed Internet in schools (Petrides, 2006). Thus, the other half of the equation is the use of data rendered from e-learning, or e-assessment, which entails using electronic technologies to drive student learning and assessment as with FA (Ridgway, McCusker, & Pead, 2004).

FA can be briefly defined as the use of diagnostic formal and informal assessments to provide feedback to teachers and students over the course of instruction for the purpose of improving performance and achievement (e.g., Black, 2015; Boston, 2002). Previous research in this area has primarily focused on traditional FA practices (e.g., paper-and-pencil quizzes), with the current literature beginning to examine the effectiveness of Internet-based, automated FA programs (e.g., Chua & Don, 2013; Kingston & Nash, 2011). The overall consensus from the traditional body of literature is that FA is an essential component of classroom procedure, and that its proper use can raise standards and achievement (e.g., Black & Wiliam, 1998a; Carlson, Borman, & Robinson, 2011; Gulikers, Biemans, Wesselink, & van der Wel, 2013; Merino & Beckman, 2010), with the latest studies of technology-based FA beginning to echo these findings. Many theories have attempted to describe FA in terms of multilevel relationships (i.e., students, teachers, schools, school districts,

etc.), with few studies focusing on statistically accounting for these nested associations, and hardly any examining technology-based FA practices (Black & Wiliam, 2009).

Regarding previous studies of online FA, the overwhelming majority of these studies have examined college-age populations in the university setting, usually within one course (e.g., Buchanan, 2000; Jenkins, 2004). In addition, past and current FA research has thoroughly examined the relationship between measures of FA and performance on a summative, usually end-of-course or final exam, but not state proficiency test scores. This area of research is just beginning to use more sophisticated statistical analyses, which is in contrast to the many qualitative studies summarizing student perceptions of a technology-based platform for quizzes/exams (Hunt, Hughes, & Rowe, 2002; Peat & Franklin, 2002). Additionally, due to the novelty of the mode of online or computerized administration, understandably research is lacking in longitudinal data analysis, with few studies examining multiple years of data across several cohorts.

METHODS

Existing DORA data were provided from one school district in Colorado from an online testing company, and existing CSAP data were provided from the same school district by the Colorado Department of Education. The data were selected via collaboration with the testing company and one school district in Colorado. The selected school district was one that gave permission to use their student demographic information and state test scores. It was necessary to have permission from both parties as the only way to examine correlated growth is to link the data via a shared student ID number. Additionally, this particular school district was selected because they had fewer missing data, with all students having graduated or left the school district at the present time. Data were linked anonymously producing four cohorts

of students across grades 3 through 11. It was hypothesized that student FA score growth will be significantly and positively related to student state test score growth.

The analytical method used was a *Two-Level Time-Varying Covariate* HLGM (Singer & Willett, 2003). According to Raudenbush and Bryk (2002), investigating a relationship with a growth trajectory of another variable of interest is common practice in multilevel modeling. Time-varying covariates are defined as person-level characteristics that are measured and may change over time, and are related to the outcome (O'Connell & McCoach, 2004). Thus, the measurements across time and other Level 1 predictors form a nested structure when combined with other student level variables (i.e., Level 2).

Time (i.e., in months with one unit being every 3 to 6 months) and DORA scores (i.e., the time-varying covariate) were used in Level 1. Demographic covariates such as gender (i.e., SEX), ethnicity (i.e., ETHNIC), SES (i.e., FREERED,

which is Free/Reduced lunch status), and ESL/ELL status were incorporated into Level 2 of the model. CSAP scores were used as the outcome variable (see Table 1). Four models were run using the DORA subtests (i.e., Word Recognition [WR], Oral Vocabulary [OV], Spelling [SP], and Reading Comprehension [RC]) as the time-varying covariate in separate models. These subtests were chosen because they did not have ceiling effects compared to the other subtests.

DATA

Existing DORA and CSAP data were used ($N = 208$) from 2004/2005 to 2009/2010 for students in grades 3 through 11. For the CSAP, students' test scores from the spring of 2005 were the first data point. Two state reading test scores were obtained before DORA implementation and three afterwards. For DORA, students' test scores from fall of 2006 represented the first data point.

Table 1. Hierarchical linear growth model level 1 and level 2 formulae and explanation of symbols

Formula Component	Explanation
Level 1 Model	$Y_{ti} = \pi_{0i} + \pi_{1i}(\text{DORA})_{ti} + \pi_{2i}(\text{Time})_{ti} + e_{ti}$
Y_{ti}	Student's CSAP score for time t for student i
$(\text{Time})_{ti}$	Elapsed years/months since DORA implementation
$(\text{DORA})_{ti}$	Time-varying predictor for a student at a given time point
π_{0i}	Intercept/Student's initial CSAP score
π_{1i}	Linear growth coefficient (for DORA)
π_{2i}	Growth rate over all years/months
e_{ti}	Individual student error
Level 2 Model	$\pi_{0i} = \beta_{00} + \beta_{01}(\text{SEX})_i + \beta_{02}(\text{ETHNIC})_i + \beta_{03}(\text{ESLELL})_i + \beta_{04}(\text{FREERED})_i + r_{0i}$ $\pi_{1i} = \beta_{10} + \beta_{11}(\text{SEX})_i + \beta_{12}(\text{ETHNIC})_i + \beta_{13}(\text{ESLELL})_i + \beta_{14}(\text{FREERED})_i + r_{1i}$ $\pi_{2i} = \beta_{20} + \beta_{21}(\text{SEX})_i + \beta_{22}(\text{ETHNIC})_i + \beta_{23}(\text{ESLELL})_i + \beta_{24}(\text{FREERED})_i + r_{2i}$
π_{0i}	Individual-specific CSAP score parameter (initial status)
π_{1i}	Individual-specific CSAP score parameter (DORA growth)
π_{2i}	Individual-specific CSAP score parameter (growth rate)
β_{00}	Baseline expectation (initial CSAP status) for the demographics coded 0
β_{10}	Expected change of the CSAP controlling for the DORA time-varying covariate
β_{20}	Expected change of the CSAP for the demographic predictors coded as 0
r_{0i}, r_{1i}, r_{2i}	Residuals

Students were tested approximately three times during the school year, with a possible total of 11 DORA assessments for the years investigated in the current study. See Table 2 for the sample demographic information.

MEASURES

DORA tests were across seven subtests: (1) High-Frequency Words, Phonics, Phonemic Awareness, Word Recognition (WR), Oral Vocabulary (OV), Spelling (SP), and Reading Comprehension (RC). With the exception of the SP subtest which is a generative test, all test items are multiple-choice. DORA results are returned as grade-level equivalencies. The CSAP is administered each spring, yielding a single, scaled score (i.e., reading score in the current study) for each student every year. The state scores were based on a scale that ranged from 0 to 1000 depending on the grade level assessed, with a score of approximately 550 as the cut-point for proficiency each year. At each grade level, students are assessed using 40 to 70 multiple choice items depending on the grade level, developed to assess student knowledge of grade-level indicators, identified as the Colorado Model Content Standards for that particular grade level. The tests across grades were vertically equated.

RESULTS

The main assumptions in Hierarchical Linear Growth Modeling pertain to the functional form of the model examining linearity, and the stochastic part of the model involving normality and homoscedasticity. Compound symmetry (i.e., a sufficient condition for sphericity; Maxwell & Delaney, 1990) can be relaxed in a multilevel framework (Raudenbush & Bryk, 2002). Linearity, normality, and homogeneity of variance (i.e., homoscedasticity), however, are assumptions that are typical of any General Linear Model (GLM) approach. Thus, these assumptions were checked

Table 2. Demographic information of the sample (N = 208) for grades 3 through 11 across the 2004/2005 to 2009/2010 academic years

Demographic Information	n (%)
Cohort	
1	47 (22.6)
2	52 (25.0)
3	48 (23.1)
4	61 (29.3)
Gender	
Male	104 (50.0)
Female	104 (50.0)
Ethnicity	
White (Non-Hispanic)	142 (68.3)
Hispanic	60 (28.8)
Black (Non-Hispanic)	3 (1.4)
Asian/Pacific Islander	2 (1.0)
American Indian/Alaskan Native	1 (.5)
Free/Reduced Lunch	
Eligible	93 (44.7)
Not Eligible	115 (55.3)
English as a Second Language/English Language Learner	
Yes	26 (12.5)
No	182 (87.5)

and upheld to ensure unbiased estimates of population effects.

The full model-building strategy was implemented for each DORA subtest as the time-varying covariate (i.e., One-way Random Effects Analysis of Variance [ANOVA], Unconditional Model, Conditional Growth Model, Full Model; Raudenbush & Bryk, 2002; Snijders & Bosker, 2012). Only the Full Models will be discussed below (see Table 3). Each column in the table provides the results from one HLGGM analysis (i.e., one per DORA subtest). The first row in the table provides the estimated average student DORA scores at Time 0, the standard error for these estimates (in parentheses), and whether the estimates were significantly greater than zero.

Table 3. Hierarchical linear growth models for Colorado Student Assessment Program (CSAP) scores and time predicting online formative assessment (Diagnostic Online Reading Assessment [DORA]) subtests ($N = 208$)

Fixed Effects	Word Recognition	Oral Vocabulary	Spelling	Reading Comprehension
Initial CSAP Status (π_{0i})				
Intercept (β_{00})	634.38 (4.94)***	632.19 (5.08)***	637.47 (4.66)***	634.33 (4.70)***
Sex (β_{01})	5.94 (6.27)	9.66 (6.17)	8.40 (5.85)	5.33 (6.03)
Ethnicity (β_{02})	-2.85 (7.80)	4.75 (7.10)	-4.49 (7.17)	3.15 (7.32)
ESL/ELL (β_{03})	-36.56 (10.51)**	-36.58 (11.23)*	-41.19 (10.30)***	-20.37 (11.35)

ESL/ELL (β_{23})	-1.18 (3.45)	1.91 (3.58)	2.69 (3.69)	-3.67 (3.98)
Free/Reduced Lunch (β_{24})	.61 (1.89)	1.09 (1.96)	2.48 (1.88)	2.42 (2.12)

Note. * $p < .05$; ** $p < .01$; *** $p < .001$. The columns are the four DORA reading subtests. ESL/ELL = English as a Second Language/English Language Learner.

All initial DORA average scores across the four subtests were significantly greater than zero. The growth rates for all subtests were significantly greater than zero. Finally, the DORA and CSAP covariation results indicated that student gain in DORA over time covaried positively and significantly with their CSAP gain on the SP and RC subtests. In comparing the growth rates for SP and RC, both were significantly positively related to the state test in reading. For every one-point increase in SP score, there was a 4.16-point increase in the state test score, and for every one-point increase in RC score, there was a 2.93-point increase in the state test score. Therefore, student performance on the SP subtest resulted in faster growth on the CSAP compared to RC.

DISCUSSION

The goal in this study was to examine if student CSAP growth is related to student DORA growth. The hypothesis was that student CSAP growth will be significantly and positively related to student DORA growth. Thus, the relationship of interest in addressing this research question is with the time-varying covariate and the state reading test. The hypothesis was partially supported in the Full Models controlling for the demographics in that the DORA scores for Spelling and RC were positively and significantly related to state reading test scores, indicating that these subtests are demonstrating a correlated growth in students reading to the state testing regardless of demographic status.

As noted in the results section, the time-varying growth rates for SP and RC from the Full Models were both significantly and positively related to the state test in reading; however, student performance on the SP subtest had faster growth on the state test compared to RC. This is an interesting finding as typically the RC subtest is viewed as the most similar in structure and content to state reading tests (Let's Go Learn, Inc. ©, 2013). The RC subtest attempts to access the semantic domain of a learner's reading abilities. Children silently read passages of increasing difficulty and answer questions about each passage immediately after they read it. The questions for each passage are broken up into three factual questions, two inferential questions, and one contextual vocabulary question. This is typically how many state reading tests structure their exams.

As indicated above, the SP subtest surprisingly was related to the fastest state test score growth rates in students. SP is a generative process as opposed to a decoding or meaning-making process as seen in most assessments of reading comprehension, which does not support the finding as noted above. Additionally, it is natural for young readers' spelling abilities to lag a few months behind their reading comprehension abilities (Bear, Invernizzi, Templeton, & Johnston, 2000). Overall, the significant findings from the Full Models indicate that as modes of online FA, SP and RC online FA subtests are related to faster state test score growth rates, with SP producing the highest growth rate.

With regards to the non-significant findings for WR and OV, it is not alarming to see that the WR subtest growth was not correlated with CSAP growth, as the testing of word identification skills out of context is typically not a skill that is the focus of standardized reading assessments (Let's Go Learn, Inc. ©, 2013). As for OV, a significant correlation between this subtest and state test score growth was expected, as a learner's knowledge of words and what they mean is an important part of the reading process (Butler, Marsh, Sheppard, & Sheppard, 1985). The knowledge of word meanings affects the extent to which the learner

comprehends what is read, such as in more traditional standardized reading tests. This subtest asks students to select the picture that correctly corresponds to a word they hear. This audio-visual format may explain the non-significant relationship between the more standardized paper-and-pencil format for most reading state tests.

SOLUTIONS AND RECOMMENDATIONS

Although causal inference is limited, the demonstrated relationship can provide teachers and administrators with evidence to warrant the continued use of technology-based FA practices. Specific to the results, the SP and RC subtests are further supported as a learning tool to gauge, or perhaps predict, student performance on the reading state test. The fact that DORA use was significantly and positively related to the state test even when student demographics were controlled, suggests that DORA SP and RC have something additional to offer.

For teachers/educators, focusing on a student's SP and RC growth can potentially add to growth on the state reading test. For example, if a teacher can raise students' DORA SP subtest score by one point, he or she can expect to see a 4.16-point increase on the reading state test on average. And if a teacher can raise students' DORA RC subtest score by one point, he or she can expect to have a 2.93-point increase on the state test (i.e., every three to six months). Thus, if a state reading test is given once a year (i.e., every 12 months) and this mode of online FA renders a one-point increase every three to six months, students' scores on the state test are predicted to grow between 8.32 and 16.64 points that year.

Teachers (and administrators) will also benefit from the results by garnering support for the use of online FA from a practical perspective. One major benefit is the ease of disseminating feedback to students after an assessment, and using the automated, specialized feedback to

diagnose problems and quickly remedy these issues in time for the state exam. Buchanan (2000) noted that the individualized feedback makes this mode of online FA ideal for large, multi-section, introductory-level college courses. In the case of the current study, this mode can also be deemed ideal for large classrooms of elementary, middle, and high school students, in which their teachers may not have the time or resources to give specialized feedback to everyone.

Another implication is the practical advantage of ease of assessment for the large number of students being tested in the educational system. For FA to be most effective, quality feedback should be provided at frequent intervals, and testing a large number of students frequently with specialized feedback can advocate the use of a technology-based mode of FA. Implications also extend to the cost surrounding mass testing. Since a positive relationship was indicated between online FA scores and state test scores, this may allow administrators to have the necessary support to purchase site licenses and invest money in such programs, which are generally cheaper to administer frequently in bulk.

For administrators, the demand for school systems, individual schools, and teachers to be accountable for student performance has increased considerably over the past two decades. This demand for accountability relates to a direct measurement of attainment of educational standards and objectives. The results from this research question support the use of online FA tools as a way to measure and attain various educational standards such as having students pass and excel on the end-of-year, summative state exam. Overall, these results provide some support for administrative demands to find more efficient ways to meet state standards. The significant and positive relationship between the scores may help get support for schools to obtain the funds needed for programs to alleviate some constraints of mass assessment.

Society, in general, benefits from these findings by demonstrating how online FA practices may have the potential to give educators a more

efficient and consistent way to make accurate, data-driven, informed decisions when evaluating student progress. This technology-enhanced efficiency has the potential to support independent student learning and facilitate future lifelong learners in our society. Rarely do teacher practices and methods have such depth of empirical support and is considered a universal best practice. Because of this widespread acceptance, evidencing how technology-based methods of FA influence achievement becomes paramount in demonstrating student learning gains and success in school and beyond.

FUTURE RESEARCH DIRECTIONS AND LIMITATIONS

Although the usefulness of correlational studies and related research questions have a place in the research process, causal conclusions cannot be stated. Future research should consider implementing a similar design, but also obtain an adequate control group. With regards to general threats to internal validity, some limitations are apparent (Cook & Campbell, 1979). Maturation is a limitation, since the existing data sampled took place over months in academic years (Kazdin, 2003). Another methodological limitation includes the use of one school district. Future studies should include multiple school districts from a range of rural and urban areas and involve public and private schools as well.

With regards to the DORA and CSAP data, the DORA data are from 2006/2007 to current and the CSAP data range from 2004/2005 to present as well. Moreover, there are more DORA time points than CSAP time points. Thus, data were not collected at the same time points (i.e., it was approximated). Generally, HLGMs can accommodate time-unstructured data such as the above; however, the accuracy and validity of results may depend on how closely the data are measured (i.e., same time/day compared to several days/weeks apart) in a time-varying covariate model (Biesanz,

Deeb-Sossa, Papadakis, Bollen, & Curran, 2004). Although this could be considered problematic, analyzing only the data points that “matched” compared to all the data did not change the substantive results.

Analyzing only students in grades 3 through 11 may be considered another weakness. Students in grades Preschool through 2 and grade 12 were not included because this study focused on the state test and regularly administered FAs, which only occur between grades 3 through 10. State testing in Colorado begins in grade 3, and grades 11 and 12 are given college preparatory exams and high school exit exams. Additionally, DORA is administered more frequently in younger grade levels, and at least three time points are necessary to analyze the data. Future studies should consider analyzing all grade levels with complete data from multiple districts.

CONCLUSION

The body of FA literature has unanimously heralded the benefits of the diagnostic use of assessment to inform curriculum and instruction, and consequently, improve student performance and achievement. Previous research in this area has primarily focused on traditional FA practices. More recently with the technology movement in schools, the literature is beginning to examine the effectiveness of Internet-based FA, with the latest studies of this modern mode FA beginning to replicate these findings. The current study attempted to add to this literature base by examining one online FA program and its relationship to a summative state proficiency test.

It was hypothesized that student online FA growth would be related to state test score growth. This hypothesis was partially supported in that these online FA scores demonstrated a correlated growth with the state test scores regardless of demographic status. The findings can provide some support to the burgeoning literature outlining the role of online FA in teaching and learning. Internet-mediated teaching and assessment

is becoming commonplace in the classroom, and is more frequently being used to replace traditional modes of student assessment. The need to examine the extent to which these methods are educationally sound is in high demand. Results from this study can not only add to the literature base theoretically and methodologically, but also practically, by bolstering support for federal initiatives and administrative demands for more efficient, technology-based ways to encourage teachers to invest their time in this mode of FA, and in turn, meet state standards and increase student achievement.

KEY TERMS AND DEFINITIONS

Covariation: Variation or variance that is correlated between two or more variables.

E-Learning: Learning that uses electronic technology or media (e.g., the Internet) to access education outside of the traditional brick and mortar classroom.

Formative Assessment: Formal and informal assessment methods conducted by educators concurrent with student learning used to adapt teaching and learning activities to improve student achievement.

Multilevel Modeling: Statistical models (e.g., generalizations of linear models such as linear regression) of parameters that vary at more than one level (e.g., nested data).

Proficiency Test: An exam that evidences how competent or skilled a student or learner is in a particular activity or field of study.

Summative Assessment: Assessment methods that are used to evaluate student learning and/or achievement at the end of an instructional cycle.

Time-Varying Covariate: This statistical term (also called a time-dependent covariate) is used in multilevel growth modeling or survival analysis, and indicates that a covariate in the growth model is not constant throughout.

INTRODUCTION

Academic libraries in the 21st century are in the midst of constant change caused by advances in technology, shifting demands of faculty and students, declining budgets, transformations in publishing and in other methods of acquiring scholarly research. Librarians working in this environment must cope with continuous change while still providing research support to their primary clientele - faculty and students. Determining the best methods of change leadership to cope with these forces is vital. As technology has increasingly impacted the workplace, best practices for leading employees through change initiatives have become increasingly common. As a new millennium is entered and the pace of change accelerates the importance of determining the best leadership styles for assisting followers in these transitions is even more imperative.

Traditionally change leadership research has fallen into two camps – those that emphasize the importance of the leader's role in facilitating change, and those that look at change leadership as a situational contingency that is moderated by traditional leadership behaviors and styles (Herold, Fedor, Caldwell, & Yi, 2008). The former approach focuses on what leaders should do when confronted with a change initiative and how to encourage followers to embrace change. This approach is typified by the work of Kotter. This article concentrates on the latter approach which believes that certain leadership styles are more useful in situations of change and is typified by the work of Bass and Riggio.

BACKGROUND

Academic libraries have been involved in a process of continuous change over the past thirty years due to the impact of technology on all aspects of librarianship. From the automated card catalog, web based database searching, remote off-campus access, streaming video, downloadable e-books, and patron driven acquisition, advances in technology have continually affected and changed the way librarians perform their jobs. These technological advances have created numerous pressures on librarians ranging from shifting job responsibilities to frequent library reorganizations.

The Disruptive Innovation Era

Libraries remained hierarchical organizations well into the 1960's. The major shift in academic library organization was the direct result of technological advances. The introduction of the computer to the library workplace was the type of "disruptive innovation" discussed by Christensen (2003) in his seminal work "The Innovator's Solution." Academic libraries adopted two new technologies which changed the workplace for librarians: first the online public access catalog (OPAC), followed by online databases. The OPAC changed the way patrons located print materials in the library. It also changed the way librarians performed their duties. By the late 1990's the majority of academic libraries had switched over to online access of databases (Kenan, 2012). An academic librarian without technological skill cannot function in the 21st century academic library.

Traditional Leadership Methods

Reinforcement/Transactional Leadership

This style is typified by the type of manager who rewards good employees and corrects poor performance with negative feedback or withholding wanted gain. This can involve various types of positive and negative reinforcement. Bass and Bass (2008) defined contingent reward as a constructive transaction. "The leader assigns a task or obtains agreement from the follower on what needs to be done and arranges for psychological or material rewards of followers in exchange for satisfactorily carrying out the assignment" (p. 623). Reinforcement leadership makes an employee's job simple – the employee is told what to do and instructed how to do it. Some employees enjoy this type of work environment – they know exactly where they stand and little independent thought or initiative is required. However, for motivated and innovative employees, such an environment can become tedious and stifling. Suwannarat (1994) found that contingent reward was the most commonly used transactional leadership behavior by library directors while active/passive management by exception was used slightly less often (p. 77).

Consultative Leadership

Consultative leadership is typified by the type of manager who asks for and encourages employee feedback but reserves the final decision making power. Consultative leadership is still quite common in many academic research libraries. Most library directors will meet with librarians when a change initiative is contemplated to receive feedback from those who will be affected. However, this type of leader tends to only accept feedback which agrees with their point of view. Negative feedback is often either ignored or punished. Library leaders who practice this style promote apathy in their followers. Librarians soon realize their opinions and expertise are not valued

and tune out from such discussions. They accept change passively or resist quietly. The deluded leaders who employ such a leadership style take the silence for agreement, when it is in fact apathy, disgruntlement and quiet resistance to change.

Contingency Theories of Leadership

There are various theories of contingency leadership which propose that the best leadership style varies with the actual situation encountered. Situational leadership dictates that different problems often require different leadership styles. Another contingency theory of leadership is the path-goal theory of leadership. Path-goal theory leadership cuts across all the leadership styles as at various times a leader may be exhibiting transactional, transformative, consultative, directive or even autocratic behaviors. It is incumbent upon the leader to select the correct leadership behavior to fit each circumstance.

Podell (2012) applied path-goal theory to academic library leadership. Ernest Shackleton was used to exemplify how path-goal theory can be utilized by library leaders. Despite having his ship crushed by ice, Shackleton was able to lead his crew to safety without the loss of a single man. Wolcott (1984) investigated path-goal theory in academic libraries and found the theory to be inapplicable. He attributed the negative results to librarians having a low need-for-independence. However, it seems more likely that criticisms of path-goal theory as being overly reliant on expectancy theory which does not account for emotional reactions to decision dilemmas or human motivations such as self-concepts were responsible for the lack of confirmation (Yukl, 2013).

Situational leadership has also been a leadership style addressed in the library literature. Dragon (1979) proposed that a new theory of leadership was needed and suggested that situational leadership could be the foundation of this new theory. Library supervisors were found to be higher on the initiating structure dimension than other groups including corporation presidents

and U.S. Senators. The library supervisors were lower on the consideration dimension than all other groups except aircraft engineers and highway patrol officers. “Subordinates in this study perceived their supervisors as behaving in ways more likely to initiate structure and bring order to their work groups than in ways which would increase the sense of group well-being” (p. 62).

Bull (2000) used the Managerial Grid to investigate leadership styles of library directors in small, Christian academic libraries. She found that there were two primary leadership styles employed in this type of academic library, and they were on exact opposite corners of the grid: impoverished and country club. Most of the directors were either task masters unconcerned with the welfare of their followers or humanitarians who put their employees first.

Mitchell (1987) found that the Contingency Model was not supported in an academic library environment (p. 94). Mitchell concluded as had other researchers that the LPC was not an effective measure of leadership style. Mitchell suggested that the reason the model was not supported was because librarians were a co-acting group rather than an interacting group (p. 101). This logic seems faulty for while academic librarians perform solo work they also perform group tasks on a daily basis. It seems more likely that the Mitchell’s findings did not support Fiedler’s Contingency Model of Leader Effectiveness because of its previously mentioned flaws.

Participatory Leadership

There are many leadership styles and behaviors that can be classified as participatory/ democratic leadership. Goleman (2002) defined a democratic leader as one who utilizes an employee’s knowledge, and creates a group commitment to the resulting goals. Despite general agreement that participatory leadership is desirable and leads to more job satisfaction and higher morale actual research findings have been spotty. Yukl (2013) believes the lack of strong, consistent research

findings is primarily the result of poor methodology or measurement limitations.

Participatory leadership has been touted as a panacea in academic libraries for many years. The team model involved more librarians in the decision making process but did not change the end result – the library director still had final say on any major decision. Many academic library directors saw team formation as a way to dismantle the unwieldy committee structure that was prevalent in large academic libraries (Nussbaumer & Merkley, 2010). The imposition of team structures lead to less participatory leadership, not more. The problems with participatory leadership were well covered by Lichtenstein (2000) “participatory management requires skill; most people need to be trained in the process; improper use of participatory management may cause serious resentment among staff; and may serve as a mask for poor leadership.” (p. 34).

Casey (2011) found that participatory management practices were either in place or being implemented in her study of strategic change in three academic libraries. She found considerable evidence of participatory management at all three schools either through a team based decision making structure or through committee activities. Strecker (2010) found that academic librarians prefer a team based structure over a hierarchical organization. Librarians felt that working in teams best assisted them in adopting and learning new technologies. While there was a preference for teamwork the vast majority of the libraries still employed a hierarchical structure.

LEADERSHIP STYLES THAT SUPPORT CHANGE

Transformational Leadership

James MacGregor Burns first proposed the theory of transformational leadership in relation to political leaders such as President John F. Kennedy in his seminal work, *Leadership* (Burns, 1978). Bass

and Riggio (2006) believed that transformational leaders “help followers grow and develop into leaders by responding to individual followers’ needs by empowering them and by aligning the objectives and goals of the individual followers, the leader, the group, and the larger organization” (p. 3). Bass proposed that there were four transformational behaviors that leaders could practice: inspirational motivation, idealized influence, intellectual stimulation, and individualized consideration (Bass & Bass, 2008).

According to Alire (2007) transformational leadership should be the most effective leadership style for academic libraries due to the need for constant change and adaptation. “Libraries are experiencing rapid change as a result of the technological transformation of society, higher education, and service delivery” (p. 171). Information seeking behavior of library patrons has also drastically changed due to competition from commercial providers (Google) and the technological competencies of Generation X and Millennials (Alire, 2007).

Hernon, Powell and Young in a two part study looked at the qualities needed to become an ARL library director. While never addressing transformational leadership directly, the list of attributes created included many transformational leadership qualities. Top valued traits included: shapes change; builds a shared vision, builds relationships, thinks outside the box, is innovative; and articulates direction - all qualities of a transformational leader.

Suwannarat (1994) measured the transformational leadership behaviors exhibited by academic library directors in ARL libraries. He found that directors primarily exhibited transformational leadership behaviors according to self-reports and their subordinate’s reports. Interestingly, “library directors were found to rate themselves significantly higher than did subordinates on idealized influence, inspirational leadership, intelligent stimulation, individualized consideration, contingent reward, extra effort and effectiveness”

(p. 102). Essentially the leaders were much more impressed with their job performance and leadership behaviors than their followers.

Baird (2010) conducted a Delphi study to look at how library deans lead their organizations during periods of frequent change in comparison with academic deans of the same institutions. There was little difference between the two types of leaders; both took actions “designed to effectively protect and lead their units” (p. 152). She pointed out a problem with current library science curricular standards, “an education that purports to prepare professionals might need to build depth and specializations, perhaps through certificate programs and post-graduate internships, to give a solid grounding in leadership theories supporting the core knowledge of library science” (p. 161).

Albritton (1993) directly compared transformational and transactional leadership styles in university libraries and their perceived effect on organizational effectiveness. Her findings were noteworthy confirming that transformational leadership behaviors were both preferred and perceived as more effective when compared to transactional leadership behaviors. One hypothesis that was supported in the research was that transformational leadership factors such as “charisma, inspiration, intellectual inspiration, and individualized consideration” when compared to transactional leadership factors such as contingent reward and management by exception would lead to “three outcome measures: extra effort of subordinates; satisfaction with leader; and leadership effectiveness” (p. 145). She also found that transformational leadership was “associated with perceptions of higher levels of planning, organizing, leading, evaluating, managing, and resource development” by respondents (p. 255). These findings correspond with Wang (2011) who found that “when a leader displays higher levels of transformational leadership, he or she will be perceived as exerting more proactive feedback seeking behaviors by subordinates” (p. 67).

Shared Leadership

Historically leadership research has centered around one individual – the leader. However, in actuality leadership is seldom about one person all great leaders have great lieutenants. Pearce and Conger (2003) point to the shifts in how work is performed, the importance of cross-functional teams to explain the rise of shared leadership. Other factors include the need for speedier leadership decisions, the fact that each employee possesses unique knowledge, expertise and skills, and that a single CEO cannot possess “all the leadership skills and knowledge necessary to guide complex organizations in a dynamic and global marketplace” (p. 2). Shared leadership should be welcomed by academic librarians. As Pearce (2004) points out “shared empowering leadership emphasizes building self-influence skills that orchestrate performance while preserving autonomy, as such, it may be particularly suited to knowledge workers, who often desire autonomy on the job” (p. 54).

Shared leadership can also mean co-leadership or tri-leadership instead of one leader. O’Toole, Galbraith and Lawler (2002) defined shared leadership in this manner. This definition of shared leadership is rather limited in that it connotes not sharing leadership with followers but merely dividing up responsibilities among leaders. The main advantage of this type of shared leadership is that it leads to smooth succession planning.

Newman (1998) called for academic librarians from within the ranks to seize the leadership opportunities available to them. His concept of shared leadership was quite limited as he pointed to collection management, library instruction, and technology as areas where academic librarians could make decisions. The idea of shared leadership in academic libraries hasn’t advanced much beyond Newman’s limited view in the past fifteen years. In a recent book Hernon (2013) has a very limited concept of shared leadership in academic libraries. Library directors should form teams, “ensure that the tasks assigned to it are clear, delineate the

team’s authority, provide stable membership over time, and monitor discreetly that team members work well together” (p. 152). This is not shared leadership it is merely replacing department heads with teams and reserving ultimate decision making power for the library director.

Franklin (1999) called for shared leadership in academic libraries. “Generally speaking, today’s college and research staff are highly educated, self-motivated, and possess specialized skills, these are all characteristics that support a shared leadership model” (p. 22). Cawthorne (2010) conducted the only study of shared leadership in academic libraries to date. He found the highest agreement with the idea that middle managers are accountable for decisions within the scope of their responsibilities. This is hardly surprising as it merely measures hierarchical decision-making authority. He found little evidence of true shared responsibility. Middle managers agreed they shared information with top managers, but many felt top managers did not reciprocate. The majority of respondents also did not agree with the statement that “ideas presented at all levels of staff in the library are equally considered” (p. 154).

A few libraries, however, have achieved some type of shared leadership. One model that has worked at Dickinson College is collegial management and rotating leadership. McKinzie (2000) states, “In 1975 the librarians at Dickinson did something that few small academic libraries have ever done, they scrapped the traditional hierarchical model of leadership, introduced a collegial pattern of management with a rotating chair, and implemented a holistic vision of librarianship” (p. 2). The librarians modeled their structure on a typical campus academic department that is run by a rotating chair. Dickinson College was the first library to adopt such a leadership model, since then several other small college libraries have followed suit. He points out there are numerous advantages to such a model - there is no possibility of being stuck long term with a bad leader since each chair serves only a three year term, all librarians

have an opportunity for leadership, every voice is given equal weight, and the image of librarians is enhanced on the campus.

Carriveau, Viers and Ziebell (2008) also touted the benefits of collaborative leadership. Ripon College decided to save money by not replacing a library director who left but instead created a tripartite governing body of department heads. Such collaborative leadership is rare in the mainly hierarchical organization of academic libraries. The benefits are many including avoiding the “departmentalization and territoriality that exists in many libraries” (p. 307).

Self-Leadership

The ultimate end of the continuum of leadership behaviors is self-directed leadership. This means that each employee is a leader, and that all workers are completely autonomous and responsible for all decision-making in their milieu. Charles Manz (1986) is the only management theorist who has advocated for what he called self-leadership. “Building on Bandura’s social learning theory, Manz argued for fostering self-planning, self-direction, self-monitoring, and self-control, which could replace otherwise needed supervision” (Bass and Bass, 2008, p. 871). However, even Manz believed that self-leadership required a superleader who would oversee all autonomous individuals. Wassenaar and Pearce (2012) believe self-leadership could be a “possible substitute for a more traditionally appointed, vertical leader” (p. 367).

Deiss (1999) in a best practices article claimed that through improving self-awareness, seeking feedback to improve performance, and creating a clear personal vision, librarians could benefit from self-leadership. However, her article did not address self-leadership as a replacement for supervision by others. Topper (2009) in a short article described self-leadership as a method of self-improvement which could lead one to be a better person and leader.

FURTHER RESEARCH DIRECTIONS

There are many areas rife for future research in the area of change leadership. One is the effect of gender on change leadership. The research seems to suggest that gender does have an impact on leadership. Men and women have different innate strengths and weaknesses in change leadership but this has yet to be empirically proven. Age is another factor that seems to affect change leadership. Some leadership behaviors seem to increase or improve with age while others decline. The biggest controversy in the research on change leadership is the nature/nurture debate. Are leadership behaviors innate or can they be developed through training? Further research needs to focus on identifying the most effective change leadership behaviors for the future. In today’s rapidly changing, globalized world behaviors that are important now may be unimportant in the near future, and little used behaviors may become vital. The impact of situation and context on change leadership styles also needs further research. Specifically on prioritizing which change leadership behaviors seem to be the most potent in the most situations.

CONCLUSION

Change leadership in academic libraries has been an understudied topic in library literature. Research methods such as ethnography, in-depth interviews, and observation allow a researcher to get a closer look at change leadership styles. Standard tools such as questionnaires mainly result in self-perceived efficacy which while interesting is not as valuable. Another difficulty not just with change leadership but with the whole area of organizational change in academic libraries is lack of measurement and assessment. Many articles are opinion based or best practices but not much literature addresses the effects of different leadership styles; nor is there much proof that organizational changes have improved service, job satisfaction, or staff morale.

KEY TERMS AND DEFINITIONS

Academic Librarians: Academic librarians are those library employees who have obtained a Masters in Library Science or a Masters in Information Science and quite often a second Master's degree in a subject discipline. Occasionally some academic librarians also possess a PhD in a subject discipline as well.

Academic Library: An academic library is a library associated with a college or university which supports the mission of the institution and the research needs of its faculty, staff and students. Although it is possible that a purely virtual library could exist, no brick and mortar institution has yet taken that step. Instead, most academic libraries consist of a physical space (usually quite large but on occasion as small as one room) and a staff of librarians and other employees that manage the building and its collections.

Academic Library Director: An academic library director is the person designated by an institution of higher education to manage a library building and its staff. Depending on the size of the institution and library this person may be designated a director, dean, provost or vice-president.

Consultative Leadership: Also known as democratic leadership, in this style leaders talk to their followers and get their input before making a decision.

Contingency Theories of Leadership: There are various contingency theories of leadership but they include Path-Goal theory, Hersey and

Blanchard's Situational Leadership theory, Blake and Mouton's Managerial Grid, and Fiedler's Contingency Model of Leader Effectiveness.

Participatory Leadership: Participatory leaders allow their followers some input into the decision-making process and often delegate some decision making to their followers.

Shared Leadership: Also called distributed leadership, it may be practiced in situations where the management of an organization is too complicated for a single individual.

Situational Leadership: Situational leadership, originally called the Life Cycle Theory of Leadership, by its progenitors Paul Hersey and Ken Blanchard, proposes that there is no best method of leadership. Instead leadership depends on the situation.

Transactional Leadership: Transactional leadership occurs when the leader rewards or disciplines the follower depending on their level of performance. Transactional leadership relies on contingent rewards or on active/passive forms of management by exception.

Transformational Leadership: Transformational leadership occurs when leaders and followers interact in a manner that raises both to higher levels of motivation and morality. Typically transformational leadership consists of four behaviors displayed by leaders: idealized influence (charisma), intellectual stimulation, individualized consideration and inspirational motivation.

L

Changing Expectations of Academic Libraries

Jennifer Ashley Wright Joe
Western Kentucky University, USA

INTRODUCTION

The digital age has fundamentally changed how academic libraries operate. With the advent of electronic resources the job descriptions and duties of librarians have expanded to include many of the same roles that IT professionals traditionally play. These roles include dealing with computers and software on a scale not seen before, as libraries attempt to stay current and relevant by adding computers to their building. How each library has risen to meet these new challenges may be different, but there are a few things that remain consistent among them. Academic libraries in the modern age are expecting a different type of education and experience from their librarians. The administration expects them to deal with virtual materials and virtual resources, which requires different skills and expertise. These libraries have also adapted their mission statements and functions to reflect the change in their resources and personnel. Some of these changes have come slowly over the last two decades, while others have come fast, but they will not be the only changes that libraries will have to endure. Technology is continuing to change at a pace not seen before in history, and patrons are expecting the library to embrace more and more of it.

BACKGROUND

Most people would say that the digital age was born with the internet. However digital technologies are much older than that, dating back to computers built in the 1960s. Libraries at this time were

using MARC records, which were digitized and are still in use today (Arms, 2012). Though digital databases and e-books were still far in the future, libraries began using this technology early on to improve the quality of the services that they were offering their patrons. Technology was used to streamline libraries on both the back end and the front end, from the records that catalogers used to the way that patrons found materials in the library. Card catalogs became obsolete as computing power increased and those records were able to be digitized. The libraries still had tons of physical materials for people to use in their research, but the digital catalog helped make it easier for people to find those materials.

In addition, telephones, not traditionally considered digital technology, helped the library answer questions without patrons having to be in the library. This was a marked change from previous interaction with patrons, because much of the traditional reference interview relies on the body language of the patron and picking up on clues that they do not know they are giving off. Without the visual cues, librarians had to sharpen their ability to hone in on problems. Just because the patron was calling with their question did not mean that they were certain about the information they needed. This remote-access librarianship paved the way for other methods of contacting librarians, including e-mail, instant messenger, and chat services. Learning from what they had done with regards to telephone interactions, librarians were able to adapt their reference interactions to serve their patron populations through these methods. While this greatly increased the contact librarians had with patrons, it did decrease the

number of people coming into the library, and that was only the start.

Technological advances led to even more new horizons for the library. When the world wide web and its contemporaries were established, they brought with them a new type of resource, the web page, which librarians had to learn how to vet for accuracy and timeliness (Arms, 2012). Though there were many contenders for what would become the internet, the World Wide Web persevered as the accepted software, albeit with many changes over time. These changes included the addition of colors and images, as well as behind-the-scenes information that could be registered within the properties of the web page, but there were still questions about the authenticity of the information being presented on many webpages. Because anyone could build a webpage, this led to misinformation and confusion among library patrons, a problem that still continues in various forms to this day. Academic libraries in their research capacity especially struggled with this problem as students began incorporating webpages into their research. Confusing the matter were many valid websites which held information that could not easily be accessed in other ways. Organizations and government departments began releasing content on the internet. Access became easy, but tracing the source became hard. Furthermore, studies at this time showed that, while students knew that the library had a webpage, and had access to the internet, those surveyed felt that the library and the internet were two separate things (D'Esposito, 1999, p. 458), leading to more concern that students were not getting the best advice when it came to research materials. At the academic library, researchers, in this case students, also had to contend with professors who would not let them use online resources for fear of misinformation. This practice of barring that type of resource led to students not fully understanding how to vet sources on the World Wide Web for their own everyday use.

Then, databases began forming to house materials that were both available in print and digitally. This led to database aggregators such as Ebscohost, JStor, and CSA. Libraries found themselves having to allocate more and more of their budgets to these electronic resources. In some ways, these database aggregators made things easier for the academic library, because digital resources were available in packages that did not initially require much thought from the librarians. However, as libraries continued to sign agreements with these aggregators, they found that there was considerable overlap in the various collections, and that dropping parts of these agreements would increase the price of the packages, essentially giving libraries less information for more money (Zimmerman, 2010). However, libraries could not afford to just drop out of the digital age entirely; students, now familiar with web searching, began expecting resources to be available to them online, without them ever having to step foot in a library. Digital technologies allowed the universities these libraries were associated with to offer classes online for the first time, swelling their enrollment numbers. However, academic libraries saw a decline in their patron numbers even as enrollment continued to grow. This juxtaposition of events required a response from the academic library.

ACADEMIC LIBRARIES RESPOND TO THE DIGITAL AGE

Early in the transition, academic libraries realized that they would need to change to continue to stay relevant. Some of these changes were relatively simple, and included adding the most popular databases as they first began, or offering technology classes for their students who had missed out on those opportunities in high school. However, as public libraries and school libraries increased their technological advancements, academic libraries found themselves having to go ever farther to keep up with the demand of the digital age.

EDUCATION AND EXPERIENCE

When the digital age first began, the Master's in Library Science (MLS) was the accepted degree for librarianship, and had been since 1924 (Kennedy, et al, 2007). Library programs taught cataloging, reference instruction, and how to prepare research guides, among other things. The focus was primarily on interaction with the patron, regardless of the level with which one was dealing. Even as technology progressed and these interactions were completed over the telephone or internet, the emphasis was still on patron interaction.

The introduction of the Master's in Information Science (MIS) and the Master's in Information and Library Science (MLIS) broadened what constituted library education. Classes offered in these programs were more technology driven, and included metadata, database search systems, and social networking, the idea being that if librarians could understand the inner workings of the technology they were dealing with, they could better assist their patron population with that technology. In many programs, these classes were offered alongside the traditionally offered programs, and would often be listed as interchangeable in the course catalog. For example, at Indiana University, in the School of Informatics (formerly the School of Library and Information Science), Representation and Organization of Information, a class that focuses on theories of classification and metadata, is offered as an alternative to the traditional cataloging class. Students enrolled in the MLS program at IU also have the opportunity to take MIS classes as electives, while many others choose to earn a dual degree in both programs.

In the present age, now that libraries are more comfortable with technology, any of the three degrees discussed can help a job seeker secure a position in an academic library. Many librarians still hold the traditional Master's in Library Science, including younger librarians, but the content of those degrees has shifted dramatically since the first library science degree was granted. About 78% of accredited programs have

some technological requirement for all students, regardless of whether these students pursue library science or information science, with 11 programs (approximately 25%) requiring technology skills before admission (Scripps-Hoekstra, Carroll & Fotis, 2014). There is an overwhelming idea that even if a future librarian is not interested in technology, there are some basic skills they will need anyway to perform certain job functions. This has proven to be very helpful in preparing them for the changes in the materials and resources that the academic library uses.

Job-listings also changed with the increase in technological demands. Libraries began recruiting librarians that had experience with electronic resources, database management, and other technological experience. The number one change in job-listings is the advent of the new position, electronic resources manager, or electronic resources librarian. Whatever the permutation of the title, these jobs require intimate knowledge of virtual resources and virtual materials on a scale that had not been seen before. Equally important to the familiarity with the resources was a familiarity with vendor language and licensing agreements that differed from the traditional print publishers. Many of the licensing agreements contain carryover language from print resources (Masango, 2005), but these agreements can be complex and daunting. Library schools accredited by the ALA have increased their technology-related course offerings in recent years (Maceli, 2015), perhaps as a response to these demands and earlier criticisms of the breadth of technological course offerings.

VIRTUAL RESOURCES

Virtual materials or electronic resources (e-resources) are now the backbone of many academic library collections. These e-resources include databases teeming with journal articles, conference papers, and book reviews, as well as e-books through various systems, and mp3s and streaming video for media collections. While the process of

collecting these materials has grown increasingly complicated over the last two decades, it was not until recently that the importance of electronic resource managers (ERMs) and management software was known. While many smaller universities struggle to catch up by hiring ERMs now, other universities were pioneers in this field. Many of them designed their own software to catalog and maintain electronic collections at a time when few, if any alternatives existed. These systems became forerunners of the electronic resource management systems that many libraries use today, but libraries are still finding that it is occasionally beneficial to create systems for themselves, because electronic resource management does not have a one-size-fits-all solution. Complicating matters is the fact that these people and systems were not deemed necessary until very late in the process. With virtual materials now taking up large amounts of the collection, both in terms of number of items and amount of money in the budget, special attention needs to be paid to the collection process.

Some materials, however, will not be digitized. There may be concerns with the process of digitizing them, or with the quality that will result from digitizing. Some digitization projects will be rejected due to copyright concerns. In these cases, there will have to be extra effort from the library to make sure their patrons are aware of what is available in the library, so that these materials are used. Still other academic libraries will have special collections, such as historical items or rare books that would not fit into the digitization model. These libraries are still a vital part of the library system at a university, and can be a great draw for researchers not just from the area but from around the globe. Marketing these physical materials alongside digital materials is vital to their continued existence. Otherwise, the materials will be deaccessioned from non-use.

The other option libraries have in the face of unused materials is to place them in archives. This is not always feasible for libraries due to budget

constraints, but it is an option to consider when faced with materials that there may not be many existing copies of. In that case, a dark archive would be the best solution. In addition to keeping these materials in the library's possession, it ensures that there will be an existing print copy of the material available to the world in the case of the online vendor going out of business. This is not only important for the institution holding the last remaining physical copy of an item, but for all libraries that would like to have continued access to items. It is, however, important to exhaust all efforts to find an extant digital copy of materials before embarking on a digitization project at the university level, because it can be costly, both in money and reputation, if mistakes are made.

There are special copyright rules associated with making copies and digitizing materials with the intent to archive them, and this can sometimes circumvent traditional copyright problems with regards to digitalization. There has been quite a bit of discussion of this in law journals since the *Authors Guild, Inc. v. Google, Inc.* case in 2013, in which Authors Guild, Inc. challenged Google, Inc.'s legal right to digitize copyrighted materials, on the grounds that Google, Inc. would be profiting from the digitization. The judge in the case ruled in Google, Inc.'s favor, citing that the in depth indexing that was the direct result of digitization was substantively transformative, because it would help researchers be able to better find books (*Authors Guild, Inc. v. Google, Inc.*, 2013). This optimistically opens the door for more digitization projects in the future, though it does not negate the time and money required for such an endeavor.

Also of particular interest in libraries when it comes to electronic resources is the cost of materials. The cost of online databases has risen steadily in the last decade and will continue to do so unless suitable alternatives are found (Zimerman, 2010). While many libraries are ready to give in to the cost and adjust their subscriptions and purchases based on it, there are alternatives already available.

One such alternative is the open access journal. The Directory of Open Access Journals lists over nine thousand journals in eighteen categories, each housing scores of smaller disciplines. Not only are these journals as good as their for-pay counterparts, but often they are actually preferred by researchers in their field, for a variety of reasons. Among these reasons are higher impact rankings and lower costs to both researchers and institutions (Joint, 2009). In addition, materials in open access journals can be supplemented by online repositories sponsored by universities. These repositories hold pre-prints of articles, as well as other materials, depending on the legal agreements the universities can make with the publisher. Many of them also house work that undergraduates and graduate students have done during their time at the university, making for a more well-rounded research body. Not only can students see what is being pursued by researchers in their field, but they can also see what work their fellow students have been doing, encouraging collaborative work within disciplines and without.

MISSION STATEMENTS AND LIBRARY FUNCTIONS

The rise of digital material required a response from the librarians out in the field doing work with patrons and acquiring and cataloging materials in technical services, but also from the administration governing these librarians. It has long been accepted that universities would have mission statements at both the university level and at the department level, which would be organized in tandem so that the university was working toward one united goal. As their roles on the university campus changed, academic libraries needed coherent mission statements that encompassed all the work that they were doing, not just their role as repositories for the physical book. Mission statements began including language about the technology, itself. For example, in Western Ken-

tucky University's mission statement, the fourth tenant is, "Maximize digital technologies and develop networked resources that enhance learning (WKU Library Advisory Council, 2013)." These new mission statements do not just deal with library technology as a burden that has to be dealt with, but as a tool for improving library resources and service. Activities that go along with these mission statements include building information commons, where students can gather and partake of information through a variety of means, including print and digital. They often also have televisions tuned to news headlines and group study areas for students to work collaboratively.

This reflects the changing library functions. What was once a quiet area for individual study is now a collaborative area filled with students working in groups to finish projects. In a way, this is just the library catching up to what has been done in the classroom for decades. Group projects had often been assigned to students in years past, and these projects were often carried out in the computer lab, or shut away somewhere in a group study room. However, libraries can, with technology, now embrace these group projects and make it easier for students to work. Now the library is a place where that work can be done easily, with access to all of the materials the group would need. Though there are librarians on duty to help students with questions, the stereotype of the shushing librarian is being shattered. This was a change necessitated by falling patron counts; as students began accessing materials on-line, libraries had to find other reasons for students to come into the library. Libraries began marketing their resources, rather than just relying on word of mouth for students to come in to the library. One of the library's best resources is the space that they provide for students to work, and this was a resource that was being underused because the space had not adapted to fit changing work demands.

Changes in how librarians view resources, and what constitutes a resource, have also facilitated

new growth in the library. Many libraries, both academic and public, have makers' spaces in which patrons can experience new technology that they might not be able to access or afford outside of the library setting. The tools that constitute makers' spaces can be either digital or physical in nature. Examples include video production software, laser cutters, and builder kits. Depending on the patron population, any or all of these might be available at the library, and are usually tailored to meet the demands of certain majors. Though maintenance and materials can be costly, these types of tools have become more resources for the library to offer, and best of all, from a statistical standpoint, they still require a physical presence in the library.

CHALLENGES TO TRADITIONAL ROLES

Some people have raised questions about the role of catalogers and reference librarians in the digital age. It is true that many of the materials acquired by the academic library are now digital and therefore come with their own records that need little to no processing, this does not signal the death of cataloging. Instead, it frees up the experienced cataloger's time, allowing them the opportunity to catalog the many and varied items that libraries might acquire that are not digital and not typical formats, such as materials used in makerspaces, in which educational resource libraries in particular are interested. This has led to a shift in how catalogers are trained, perhaps, but not a change in their necessity; in an interview, Allyson Carlyle, an associate professor at the University of Washington, emphasizes a focus on the teaching catalogers how to think in the best ways for cataloguing, rather than teaching them the rote behaviors of cataloging (Dull and Parks, 2011).

Reference librarians, too, have seen some changes to their job roles. More of an emphasis has been placed, for example, on curating collections, as the balance of print resources and electronic resources is more important than ever

(Terrell, 2015). It is up to the reference librarian to sort through not only information but also information sources, and deliver those that meet their approval to their patrons. It is also imperative that reference librarians become instructors, instructing their patrons on the appropriate ways to find information and how to vet it; patrons may be able to use search engines for answers, but they need help in selecting the best answer.

FUTURE RESEARCH DIRECTIONS

The challenges that libraries face today could potentially sound the death knell for smaller academic libraries. Students no longer believe that libraries have the monopoly on research materials, and they are right. Google scholar has become a serious challenge to libraries despite a pushback against it from librarians, because it is attached to a name that nearly everyone knows—Google. Most students, especially undergraduates, can find the materials they need for their class projects from the comfort of their own home computer. Part of the way to combat this problem is to embrace the supposed enemy. Google scholar can be a very effective tool when used properly, and if a student has the system set up correctly, they can even use Google Scholars' search features to search their own libraries. This search feature has been immensely popular with students, but it is not the only thing they need when they research. Other databases are still important to the research process and may have search interfaces more suited to the search topic at hand. Libraries have to become creative when trying to draw in students to their libraries and to use their resources.

Drawing students into the library can be accomplished through a strong connection to the faculty. Students see faculty every day and are more likely to take their advice when it comes to research and their grades. Set up library instruction sessions for classes, and be sure the students know what's in it for them when they attend. Explain to the student what the difference between searching in Google

and searching in a database is, and how the latter can actually be easier and quicker to do once they know how to do it. Running through search questions in the various databases can demonstrate to them the different types of results that they can get. Furthermore, it will show them that difficulty sometimes presented in retrieving materials when one is not logged in to a university database.

Other suggestions for making a library more inviting and adaptable to the changing digital world include creating collaborative learning spaces that integrate technology with the learning experience, adding outlets and power stations to facilitate the use of laptops, tablets, and other portable electronic devices. Information commons like the one discussed here are an excellent way to facilitate this change and are very popular subjects for funding and grants at this time. They provide a seamless entrance for the library into the world of technology and provide a valuable resource for the students. Furthermore, if a campus has a technology center that is not part of the university library system, an information common can artfully redirect traffic back to the library that the library might be losing to other sources that seem to be more convenient. This is in turn better for the students, who will have academic librarians on hand to answer questions when or if they arise, making the research process easier and encouraging them to continue their studies without getting discouraged.

All of the change that has occurred in libraries, and all of the change that is still yet to come, requires a change in how success is measured. A library whose success is measured by the number of people walking through their physical gates and using their brick-and-mortar building is going to be disappointed by the numbers that they see, even if those numbers are bolstered by things like information commons. Universities are being more flexible with their class models, offering more classes online, and therefore many people may never step foot on the university campus, much less in the university library. Rather than letting these students languish, struggling on their own to

accomplish research while their counterparts on campus have all the help they could want, university libraries should be working with advisors and classes to make sure that they are also reaching out to these students. There are a variety of ways that this can be done, including web tutorials, research guides, and videotaped presentations on library resources that can be embedded in the software that the university uses for their online classes. The tools to reach these students are available, and helping them should count in statistics, even if they are not coming to the university. All ways that the university resources are accessed should be given equal weight, because the university is still providing a valuable service, whether librarians are conversing with patrons through email, on the telephone, or in face-to-face interactions. Even keeping track of patrons accessing virtual resources through OpenURL can be an eye-opener to the way that the academic library is helping their students (Wright, 2014).

CONCLUSION

Today's library exists in a very different world from the days when they first became popular. Much of the library's content is digital, and can be accessed online. Some materials, however, cannot be digitized at this time because of technical or copyright concerns. Identifying these materials and integrating them into the curriculum is important for their continued value and to increase patron counts in libraries. Equally important to libraries is the constant innovation of new resources and outreach methods to serve the patron population. Changing how they measure success will also help libraries justify and evaluate programs, because it will highlight the way that their services have changed over the years. For the most part, libraries are already keeping track of statistics in many and varied ways, and acknowledging that these changes exist. However, they are not doing enough to put more emphasis on those reference interactions and that resource usage, when they

should be. By embracing the digital age, libraries will survive and thrive far into the future.

KEY TERMS AND DEFINITIONS

Academic Libraries: Libraries affiliated with universities or colleges.

Digital Age: From about 1980 on, coinciding with the advent of the World Wide Web.

Digitization: Scanning or otherwise manipulating print materials into an electronic format.

Electronic Resources: Library materials available in an electronic format.

Mission Statement: Unified theory, plan, or goal of an organization or subsection of the organization.

Digital Archives for Preserving and Communicating Architectural Drawings

Roberta Spallone

Politecnico di Torino, Italy

Francesca Paluan

Politecnico di Torino, Italy

INTRODUCTION

Archives created by architects are unique and significant sources for scientific research in understanding architecture in all its features connected with multiple disciplines (history of architecture and representation, conservation, city planning and landscape). Contemporary architectural archives contain relations which cannot easily be read and contextualized because of the documents organization and order, given by the archival necessities and the producers themselves. According to the archival science, the documents reorganization is forbidden even if it could be helpful for their analyses. As researchers in the architectural representation field, the authors believe that the mere digitization of archival drawings is not sufficient to transmit the potential of knowledge and meaning that it is caught by the direct study of the sources. The use of digital databases at microscopic and macroscopic scale allows the contextualization of the archival data, in order to help the public to elaborate information and acquire new relations. The authors investigate this phenomenon underlining the benefits and the risks connected to the digitization of the contemporary architectural archives, focusing on their communicative potentialities thanks to the tools of the digital representation, in relation to the necessities of fruition and preservation of the original archival materials.

BACKGROUND

Contemporary architectural archives constitute more than a documentary heritage, recently recognized and validated (Domenichini & Tonicello, 2004). Since the end of the Seventies, effectively, the principal North-American and North-European institutions engaged in the knowledge and diffusion of Architecture have been working hard and more carefully into conservation and enhancement of contemporary architectural drawings, which need specific standards for their description, preservation and fruition guaranteed by international associations, like the ICAM (International Confederation of Architectural Museums) and the ICA (International Council on Archives) since 1979.

The international archives take part to the ICA, whereas the archival cooperation in the European Union sphere is developed by a working group called European Archives Group (EAG), born in 2006.

Such a recent interest about the architectural documentary heritage, in fact, is carried out by different fields of research that starts from the analysis of the drawings and is elaborated according to numerous purposes, the study of the representation, the history of architecture and city planning. Its value is moreover justified by the same meaning taken: in addition to being a proof of a phase in the design process and a historical

memory, the drawing may be considered a useful document to the reconstruction of the events happened to an artifact, or it could be evaluated as a work of art. For this motive, in the same years various institutions arose, engaged in the promotion and fruition of architecture in general, and particularly focused on the safeguard of the documentary heritage, made up of heterogeneous material. This trend, still of north European and North American origin, led to the foundation of museums or hybrid structures containing collections of architectural documents. Because of the documents complexity and heterogeneity, the need to establish new descriptive standard of the objects was immediately felt within the cataloging range. On the international level, the current state provides for standard (taken from the Library System and Document) derived initially from the archival cataloging specifications and gradually structured according to the new descriptive requirements for the architectural documents. Currently the standards most commonly used are those dictated by the International Council on Archives, such as: the ISAD (G), that is the General International Standard Archival Description; the ISAAR (CPF), that is the International Standard Archival Authority Record for Corporate Bodies, Persons and Families; the ISDIAH that is the International Standard for Describing Institutions with Archival Holdings (Ministero per i beni e le attività culturali, Direzione generale per gli archivi & Servizio documentazione e pubblicazioni archivistiche, 2003).

Since the nineties, the archival administration has arranged multiple informative systems, which matter as a kind of computerized registry of the archives.

The difficulties of managing information concerning the architectural documents arise from the different materials constituting this cultural heritage: not only drawings and correspondence, but pictures, scale models, audio and video recordings. The collections have been therefore expanded and layered as new materials have been introduced as support to the architects' project activities.

Since the twentieth century, the traditional paper supports have been juxtaposed by other types of support, including acetates and derivatives from plastics. Another new type of worksheets has been introduced by the technologies and software for the architectural representation since the early nineties. These innovations have led to significant impact not only in the design phases, but also in the products in the matter of architectural drawings in digital formats. This phenomenon has involved the formulation of other cataloging approaches, as well as preservative and communicative strategies.

For this reason, several international projects have been activated to study the phenomenon of cataloging and preservation of the architectural design files born in digital format.

Among these plans, the International Research on Permanent Authentic Records in Electronic Systems (InterPARES) aims at "developing the knowledge essential to the long-term preservation of authentic records created and/or maintained in digital form and providing the basis for standards, policies, strategies and plans of action capable of ensuring the longevity of such material and the ability of its users to trust its authenticity" (www.interpares.org). This program, trained by the School of Library, the Archival and Information Studies at the University Of British Columbia, in Vancouver, has already developed four steps of research since 1998.

The archives of contemporary architecture are organized according to a structure in which the material is interfaced with the public, in accordance with the shared methodologies for the data search. The first research means that the user has to consult is the catalog of the archival groups that is an ordered and systematic list of the archival units (the individual documents) with sufficient details to identify them. This search tool is structured according to the database, a data archive of the archive itself relating to the same topic or more correlated to each other, whose management - which involves the entry, modification and research operations - is fulfilled by means of dedicated software. These databases are managed

by the DBMS (Database Management System), systems for the administration of large amounts of data that could be shared by several applications and a plurality of users, which could be increased without restrictions, supporting natively the multi-tasking and networking (Bartolomei, 2001, p. 97).

The catalog of a database system stores the metadata of each object inserted. “Metadata is a structured information that describes, explains, locates, or otherwise makes it easier to retrieve, use, or manage an information resource” (Guenther & Radebaugh, 2004).

In an architectural archive, as in other fields, metadata could be descriptive, improving the research and the identification of the object they refer to; structural, listing the object compounds; administrative, containing technical information about the rights management and preservation of the resource. For this reason, even architectural archives have developed a strict organogram made up of different groups facing with the different aspects of cataloging. Such structure is significant because it expresses the main actual challenges to be faced: the archive management complexity related also to the digital assessment, both in static (web pages, with the names and locations of the resources “hard-coded” in the HTML) and dynamic form (thanks to specific tools supporting web applications able to extract and manipulate the information). However, metadata stored in a digital database “can help organize electronic resources, facilitate inter-operability and legacy resource integration, provide digital identification and support archiving and preservation” (Guenther & Radebaugh 2004). On the other hand, a database is more susceptible to the technological obsolescence and intentional, or unintentional, alteration, the same as the digital “objects” collected in the archive. The linked open data (LOD) about the theme of the web of data (semantic web) are currently being examined as part of the technical-computer and librarian academic field, in the North America and North Europe, as a tool for the linking of Cultural Heritage information for libraries, archives and museums, through ap-

plications that can query data, drawing inferences using vocabularies (Mazzini & Ricci, 2011).

MAIN FOCUS OF THE ARTICLE

Issues, Controversies, Problems

In the course of time, documents of architecture present different support typologies and data characters, providing insights for numerous possible interpretations.

The need for standardization in the cataloging process, required not only to the interoperability between archives and institutions, but also to facilitate the finding information clashes with a wide variety of materials in the archives of contemporary architecture, sometimes hardly recognizable in their material and graphic composition. The diversification of supports, graphic and photocopying techniques, in fact, is made more difficult to understand since the technical and technological innovations have been introduced in the design studios. The archives of contemporary architecture are defined on the basis of the project activities and are differentiated in the time and the needs of the works. Consequently, each architectural archive represents a reality per se, both for the composition and the extension of the documentary corpus, both for the arrangement and the organizing ways adopted for it. Therefore, the study of an architectural archive involves primarily the recognition of the material preserved, as well as to understand and place each document into the project refers to, as a product of architecture, engineering, city planning and design: so the skills of the archivist and the architect are essential. Therefore, also with regard to the filing, the documents heterogeneity requires the adoption of specific methodologies of cataloging, differentiating materials into: graphic ones (sketches, preparatory and/or demonstrative drawings, and survey and design tables, cartographic material and preliminary documentation); textual ones (loose papers or collected in envelopes and files,

manuscripts and typescripts bound or not, administrative documents, correspondence, advertising or documentary material, extracts from magazines, clippings, books); photographic ones (positive and negative on paper, film, glass); digital ones (audio and video recordings, computer files on various media); objects (scale models and sculptures, tools used in professional activity, paintings, samples of materials). These types could be grouped as aid materials for work or as products under preparation phase (design, definition, execution, construction site); they could be made also for different purposes (competitions, contracts, promotions) and customers (private or public). Since the twentieth century, the material traditionally used in the preparation of the architectural drawings, has been juxtaposed by new supports and techniques. In addition, the same paper differs significantly in its composition depending on the era it was produced in. The same argument is valid to the tracing papers, which differ mainly with the introduction of new materials and related techniques of graphic reproduction. So, in a contemporary architectural archive there are miscellaneous materials, including: traditional paper, cardboard, tracing paper of different matrix (traditional and/or tissue paper, vegetal parchment, etc.), sheets of acetate. Even the graphic techniques of the architectural drawing are extremely varied (pencil, charcoal, pastels, inks of various types, etc.), sometimes of artistic origin. Another peculiar aspect of the contemporary architectural archives is the use of the reproduction techniques of the drawings, necessary for the project activities: the need to represent quickly different executive variations has involved the drawings duplication using techniques that have appeared since the twentieth century, resulting from the evolution of photography and the research on light-sensitive substances. Therefore, in an architectural archive, multiple copies of the same drawing could be often grouped, made by means of different techniques such as the blueprint, the ectography (or aniline process), the heliography (or diazotypes) and the xerography, that lend themselves to the use of other supports than the traditional ones. The radex corresponds

to this case, because it is a heliography print on a polyester sheet. The architectural documents, also, show a series of infographic data that should be interpreted. In relation to the design practice and representation techniques these data refer to, drawings transmit information in a univocal manner as regulated by certain standards such as the representation scale, orientation, size, dimensions, thickness of lines, etc. In this context, the interpretation of the drawing is oriented towards an unequivocal direction for the identification of the graphic message, while the interpretation given by the public may be released according to the different branches of research (design, historical, etc.). An enhancement strategy adopted in the management of architectural archives is the communication, with multiple strategies and outcomes, however made difficult by the nature of the archive itself, often inaccessible or difficult to reach, where the documents could not be always consulted, risking the loss.

Architectural digital archives, as well as they provide research systems that could be queried to find the documents, are managed by methodologies useful to the safeguard and enhancement. The knowledge of the archive is the first key moment of safeguarding: for their constitution, archives are the containers of information not to be easily grouped without a direct survey of the institutions dedicated to the fruition. The first step to the knowledge is the catalog consulting; this initial research, even if it is remotely conducted, usually provides the descriptive metadata of the objects. Although this information is essential to the identification, often documents cannot be remotely accessed, because of their lacking digitization. In the case that the architectural drawings are inserted into the digital databases, the files displaying turns out to be quite unsuited to the research and study of the document, because the file of the image display, rarely downloadable, has a low-resolution, preventing the reading of the graphical information. In addition to the inadequate understanding of the graphic message, the lack of the dimensional scale prevents the recognition of the drawing dimen-

sions and the presence of the written measures may be relatively useful if they are insufficiently visible. These considerations emerge during the web navigation. The scanned drawings could be sometimes downloaded; however, also in this case the resolution remains most often inadequate. Despite the innovative technologies related to the scanning offer ever more efficient performance, the architectural drawing inserted in the database remains an icon that could be partially zoomed in. These limits are attributable to several factors: if the images are bound by strict regulations of copyright which force the user to a superficial study of the drawing, on the other hand the costs of digitization of whole architectural archives are still too high. The transition from the analog source to the digital product by the scanning produces files with different mass-diffusion standard extensions (.pdf,.tiff,.jpeg,.png), thus promoting the dissemination of the material to a wide public.

Photographic digital reproduction can be considered an operation of preventive conservation with two purposes: to avoid the damage resulting from the direct consultation and an unsuitable handling of the drawings, and to create security copies available for the production of “packages” for traveling exhibits, in place of the exposure of the original drawings. This procedure was adopted and promoted in Italy by the Centro Archivi, which has defined three levels of photographic definition of archival drawings: 300 dpi in full scale TIFF as facsimile, with the metric and chromatic scale; 150 dpi-1062 pixels JPG, 72 dpi-510 pixels JPG (Pesce, 2009).

Another factor inducing the institutions dealing with the safeguard and enhancement of the contemporary architectural archives to redefine the preservation and communication strategies is the presence of documents in digital format, extremely fragile from the point of view of the permanent preservation. Their use is bound by the characteristics of digital information (authenticity of the original digital file as a copy on the web, maintaining the functionality of the design produced by the interactive software). In this sense,

international conferences are promoted as the place and opportunity to debate about the hybrid archives management, trying to develop projects related to the archives digitization and their fruition in the virtual environment (Peyceré & Wierre, 2008). In Europe, the European Archives Group is active in the dissemination of the archival heritage, even the specific one about contemporary architecture. In that sense, a portal has been created for the research in all the European archives, called Archives Portal Europe, in which cultural heritage related to the architects and engineers' archives is expected as one of the topics. One aspect that EAG would advance is the collaboration with Europeana, for the archival documentation made accessible and searchable in the multidisciplinary context of cultural heritage conveyed by archives, museums and audiovisual online collections. At the moment, Europeana is in an expansion phase with regard to the disclosure of the contemporary architectural archives.

The case study of the Italian archival heritage, characterized at the same time by a large amount of materials (due to its unique historical and architectural tradition) and an accentuated fragmentation, lends itself to interesting in-depth analysis. Because of the extreme fragmentation characterizing the Italian heritage, widely diffused throughout the territory and therefore managed according to a polycentric model, other enhancement strategies have been adopted on the premise of making archival resources accessible, historically contextualized, to a wider public (Maiello, 2013). One approach useful to such disclosure is the creation and management of archival networks.

The exhibition of drawings from the architectural archives is, finally, another way of promotion and divulgation of such fragile heritage. The physical exposure, however, is not always practicable especially for preservative reasons (extreme fragility of the works, impossibility of their mobilization into other spaces). For this motive, the online virtual exhibitions fulfill effectively this purpose, allowing the physical safeguard of the drawings and the active participation of visi-

tors in a multimedia and interactive exhibition. In this context, the technological development in the telecommunications and computer graphics field has made possible new teaching experience approaches in the cultural heritage fruition, using the Web or mobile devices to display also digital products such as animations, applications for immersive experience of virtual and augmented reality (Christmas & Saccoccio, 2012). In the case of the archives of contemporary architecture, digital objects can be scanned drawings or three-dimensionally rendered ones, linked by a theme, made accessible thanks to technologies currently available through an architecture of system designed to offer the users engaging experiences. The result is the creation of dynamic products, updatable also by the public involved in the resources exploration according to free interpretative readings. The on-line virtual exhibition is also developed according to thematic itineraries that are paths that allow the public an extremely independent approach in

relation to the space-time location and the origin of the documents. Actually, a kit dedicated to the creation of online virtual exhibitions exploiting the open source software has been developed, taking advantages of the Web potentialities to make the invisible visible and available this sector of cultural heritage risking the oblivion, such as the extremely scattered architectural drawings in public and private archives.

SOLUTIONS AND RECOMMENDATIONS

From the point of view of the architectural representation research, the authors believe that the knowledge data, resulting from the direct documentation analysis, needs to be interpreted, represented and communicated (Spallone & Paluan, 2015).

Figure 1. Lancia Office Building, 1954, elevation and cross section (Archivio Rosani, Laboratorio Beni Culturali - Politecnico di Torino)

The digital model could be an effective database for collecting and synthesizing these analyses.

The extreme care in implementing 3D reconstructions is the final result of a new attention paid by the stakeholders to the communication capability of information technologies, both as for the large audience and the narrow scientific community. The simplest language is required to the producers of these models (De Francesco & D'Andrea, 2008), in order to share and diffuse information in a readily understandable form to a wide-ranging spectrum of public. Thanks to these models, the era of graphic papers that only specialists can decipher is over.

The authors are carrying out a research project in which they propose methodologies and techniques that can actively contribute to widen the knowledge and the understanding of Archival

Drawings, intended as Cultural Heritage, and support their sharing, in the firm conviction that safeguard and fruition should go together.

The analytic activities start from reconstruction, through the graphical analysis and the re-drawing of the archival drawings, possibly supplemented by other documentary sources, which can enrich the mainly geometric data arising from technical drawings, and could provide information on colors, building materials and techniques and characteristics of the original surrounding environment.

During this representation phase, the re-drawing of plans, elevations and sections involves the check of projective correspondences, aimed to three-dimensional synthesis, and the possible need to interpret inconsistencies and blanks. In this way the act of modeling may enhance knowl-

Figure 2. L'Oréal-Saipo plants in Settimo Torinese, 1959, perspective view, plans, elevations and cross-section (Archivio Rosani, Laboratorio Beni Culturali - Politecnico di Torino)

Figure 3. L'Oreal-Monsavon plants in Aulnay-sous-Bois, 1958, perspective view and sections (Archivio Rosani, Laboratorio Beni Culturali - Politecnico di Torino)

Figure 4. L'Oreal-Monsavon plants in Aulnay-sous-Bois, digital reconstruction (Digital drawings and 3D model by Francesca Paluan)

edge acquisition, not only for others, but for the modeler as well (Vandevyvere, Neuckermans, & De Jonge, 2005).

Regarding the next stages of modeling, the drawings created are the basis of the 'blue-prints technique', in which the two-dimensional drawings which write-up archive drawings in vector format are placed on orthogonal planes in the space of the digital work, so they can directly infer the geometric and dimensional references.

This methodology has been applied to Rosani Industrial Architectural Studio's archive, since the Fifties mainly involved in projects for major

and medium-sized industries based in Italy and abroad, with the collaboration of several masters of contemporary architecture, such as Giò Ponti on the design of Lancia Office Building in Turin, Carlo Mollino on the complex INA CASA in corso Sebastopoli and Pierluigi Nervi on the plants of L'Oreal in Settimo Torinese.

Rosani's archive collects a historical and cultural heritage today in danger of dispersion and forgetfulness: consultation is reserved for few experts, a non-specialist potential public cannot immediately understand the data, the planned buildings are earmarked mainly for the industrial

Figure 5. Salina de Araya, Venezuela, 1957, perspective view, plan, elevation and cross-section

use, so they are difficultly communicable because they represent an economic and social logic little different from the Cultural Heritage is generally subjected to. The hypothesis of a physical exhibition of the drawings considered the most exemplar would be a temporary event that will surely enhance the archive, but then it could not guarantee a return of interest from the public.

These reasons let hypothesize and, if possible, apply the strategies considered the most suitable for the enhancement and the safeguard, through the representation techniques and methodologies for the interpretation and communication of the projects. These objectives, under development, will be the basis of a meta-project Rosani's archive will be made ready for.

The magnitude of the archival collection obliged to focus only on some of the most significant projects by Nino Rosani. The selection was conducted according to certain parameters: the exemplarity of the plans; the existence of design variants; the inaccessibility of the existing building (because it is still in use), and the importance of transformations and expansions on the structure over time.

FUTURE RESEARCH DIRECTIONS

The process launched by the more advanced ICT about enhancement strategies of Cultural Heritage through communicative plans, is also applicable to

Figure 6. Salina de Araya, Venezuela, 1957, digital reconstruction (Digital drawings and 3D model by Francesca Paluan)

the archival heritage of contemporary architecture, partially digital born and designed to exploit the interactivity and multitasking from the beginning (Garagnani, 2010). Digitization is a subject of debate among the various institutions, so that drawing unequivocal conclusions that could be applied to the different areas of expertise is still impossible. The need to address this issue arises from the awareness that about the 80% of digital documents created in the nineties will be (or has been) lost due to the rapid technological evolution whose preservation problems have not been solved yet. The digitization of the architectural archival heritage is penalized by the high initial costs and software and hardware maintenance for data management, but it is a potential storage medium that ensures the enhancement broadening the range of public, running as security storage of information. The use of ICT is not necessarily limited to the communication: its propensity as a means of education facilitates the learning thanks to the immediacy of message delivery and the simultaneous establishment of hyperlinks.

CONCLUSION

Architectural digital archives have been established to prevent the risk of their dispersion and oblivion: the fragility of such cultural heritage depends on the low visibility except for a highly specialized field. Digitization is therefore an approach that first tries to make recognizable this hidden heritage, making it available to an increasingly connected public. Breaking down the barriers of space through navigation and remote access to the data and the temporal ones through the devices running in real time, the possibility to view documents is finally satisfied, although such documents are not always equipped with the information to a more specific analysis regarding the iconographic message.

KEY TERMS AND DEFINITIONS

Architectural Document: The first definition was formulated in the conference "Towards standards for Architectural Archives" in Washington DC in 1982, with the participation of the International Confederation of Architectural Museums, the International Council of Museums, the International Council of Monuments and Sites, the Union International des Architects and UNESCO. It "designates any documentary material and anything annexed to it being correlated to the history, the theory and the practice of Architecture and the domains connected, whichever are the supports and the physical features [...] created or received by public or private entities during their activities and [...] collected, wherever it comes from".

Archive: It could be defined as a collection of historical documents or records containing information about and relations with a person, a group of people, institution, place; it is also the place where such documents are kept. It is a Cultural Heritage to be preserved and enhanced in order to safeguard the memory it is the depository of.

Database: A data archive about the same subject or a set of subjects connected one to each other, managed by dedicated software. The data are defined as metadata such as they identify and describe the resources and giving location information.

Descriptive Unit: A component of a finding aid to be used for searching. It is usually one record – or a group of records – within a fond, which is described by at least title, date of creation and reference code.

Digital Object: A digital representation of archival materials. It could be an image, text, sound, video, 3D. It could be also the original object when born digital.

Fond: An aggregation of documents that originates from the same source.

Intelligent Systems and Creative Industries for Cultural Heritage: Important and integral parts of systems that support product design for the Cultural Heritage knowledge, fruition and divulgation. The Marcus Institute for Digital Educational in the Arts (MIDEA) illustrated and identified the potentialities of the emerging technologies for the learning in the Horizon Report in 2010, focusing on the area of the mobile and social media, augmented and virtual reality, localization systems, the semantic web and the action computing.

Massive Digital Libraries (MDLs)

Andrew Philip Weiss

California State University – Northridge, USA

INTRODUCTION

To provide a clearer framework for analyzing the growth of digital libraries, Weiss and James have proposed the term Massive Digital Libraries (MDLs), which is based on the size, scope and increasing scalability of digitized book collections. Such MDLs rival the size, breadth, and depth of a physical library's print holdings, and often reach a scale seen among library consortia collections. (Weiss and James, 2013a, 2013b, 2014, 2015; Weiss, 2016)

The root of the concept begins in late 2004 when Google made its “resounding announcement” to digitize millions of the world’s books—including works still under copyright protection—and to place them *all* online. (Jeanneney, 2005) Jean-Noel Jeanneney, head of Bibliothèque nationale de France at the time, interpreted Google’s planned project as a wake-up call for European countries. Failure to catch up to the American company, he argued, would result in significant problems for non-American organizations.

Twelve years on, it is hard to imagine that Google’s desire to create an online digital library on such a large scale should have come as such a shock. Yet at the time Google caused significant hand-wringing and soul-searching among institutions traditionally charged with producing or preserving cultural artifacts. (Jeanneney; Venkatraman, 2009) In retrospect, the controversy seems almost quaint in comparison to the current crop of issues – especially the current “disruptions” of established economic models by Uber/Lyft, Facebook, Twitter, Spotify, Snapchat, e-readers, et al. and the encroachments on civil rights via electronic digital surveillance and other intrusions of privacy.

DOI: 10.4018/978-1-5225-2255-3.ch454

A number of mass-digitization projects have grown in the wake of Google’s announcement, including the *HathiTrust*, *Internet Archive*, *Digital Public Library of America (DPLA)*, *California Digital Library*, *Texas Digital Library*, *Gallica*, and *Europeana*. These projects each transcend their roots as localized digital libraries and have simultaneously adapted to and altered the digital landscape. These various MDLs have allowed for and contributed to the ascendancy of our current mass-digitization online culture.

This chapter will describe the characteristics of Massive Digital Libraries (MDLs) and outline their impact upon contemporary information science issues, especially with regard to digital collection metadata, copyright and the diversity of the source collections. Traditionally, libraries have been created to serve particular communities defined by geography, intellectual discipline, or specific end users. However, MDLs in their current trajectories promise—for better *and* for worse—to transcend such limits.

BACKGROUND: DEFINING MASSIVE DIGITAL LIBRARIES

Defining Criteria

Massive Digital Libraries (MDLs) describes a specific class of digital libraries that correspond to the size of a traditional, large brick-and-mortar library. Although other disciplines have discussed digital libraries and archives in terms of computer science, such as in the Very Large Digital Library (VLDL) movement, none have framed the discussion in terms of the principles of library science

or the services and content access provided by an actual, working library. (VLDL, 2011)

The following list of characteristics has been proposed to help define MDLs:

1. *Collection size: surpasses 500,000 texts; prime MDLs comprise tens of millions of texts;*
2. *Acquisitions, collection development & copyright: numerous partnering members contribute content regardless of author or copyright holder permissions and regardless of end-user needs;*
3. *Content type: mass-digitized print books; the resulting searchable digital corpus of texts becomes as important as the individual titles;*
4. *Collection diversity: diversity is dependent upon self-chosen partner members, which can reflect distortions or biases inherent to the source collections;*
5. *Content access: varying degrees of open access exist within MDLs; content is searchable through single, uniform interfaces (search engines & portals) representing all the collections as members of a single entity regardless of source;*
6. *Metadata: Metadata is gathered and aggregated from multiple sources, with a reliance on new digital description schema;*
7. *Content / digital preservation: consortium members provide long-term digital preservation strategies at local levels as well as “in the cloud”.*

These criteria and their attendant issues, though not necessarily unique to digital libraries, require different approaches when dealing with a Massive Digital Library. The issues involved with aggregating millions of previously published print materials into one uniform, yet decentralized, conceptual and online digital space become more complex as size increases. It is important to differentiate MDLs from their smaller counterparts as they are more difficult to police and analyze, especially

with metadata uniformity, copyright compliance and rights ownership. The larger the institution or system the more unwieldy and slow-to-change it may become. It is therefore important to remain cognizant of how these MDLs approach the common characteristics of books in ways that stretch the boundaries of the original print medium. Print books, for better or worse, remain static during their lifetimes, changing only when new editions are created. Yet e-books could change into ongoing “works in progress”; they can be altered with relative ease. Identifying MDLs as unique entities would allow scholars and researchers to both utilize and safeguard these newly-created digital corpuses.

REPRESENTATIVE MDLS

The following is a look at several representative MDLs and their defining characteristics. This section will also help readers get a sense of how MDLs stack up against each other. Criteria described for each MDL include their starting dates, *modus operandi*, estimated sizes of the collections, subjects collected, the number of partner institutions, and the languages covered in their collections.

American-Based, Anglo-Centric MDLs

Google Books (25 Million Texts)

The *Google Books* project started in 2004. Envisioned by Google co-founder Sergei Brin as the replacement of a library’s card catalog, *Google Books* currently holds approximately 25 million volumes within its collections, though exact figures have been difficult to verify.

Google Books is characterized in part by its extremely robust and flexible search engine. When searching in this MDL, a large amount of set results will often appear. Mistakes in the search are often auto-corrected. Their stated goal

is the digitization of all the books in the world, a number that reaches about 129,864,880. (Jackson, 2010) They work with authors directly through their Google Books Partner Program and with public organizations through their Google Books Library Project, which includes about 22 public and academic institutions and consortia from several countries, including Japan, Germany, England, and Spain. (Sato, 2010) Overall collection diversity is represented with a large number of languages represented and accessible, though the bulk of the source material in the digitized corpus is in English.

The *Google Books* corpus is open to anyone able to use a computer that is connected to the Internet. However, due to copyright restrictions and the threat of litigation, any materials falling outside the public domain have been closed to full-text viewing. Google provides users with three levels of accessibility to the texts beyond the basic metadata record: 1) Snippet View, which is a few sentences of the book, 2) Partial view, which is often several to dozens of pages, and 3) Full view, which is the complete text. Additionally, Google has provided access to the data sets from the digitized corpus for researchers to utilize. One of the most promising tools developed for this text mining is the Google Ngram viewer.

HathiTrust (14.6 Million Texts)

HathiTrust started in 2008. It currently holds 14.6 million volumes (representing 7.3 million unique titles) within its collections; 5.6 million volumes (38% of the total) are in the public domain. The *HathiTrust's* main goal is to meet the needs of the members of its partnering institutions. These partners include nearly 72 world-class academic research and national libraries. Notable partners include the Library of Congress and the California Digital Library. Collection development is focused on gathering digitized books and journals from partner institutions and in-house digital initiatives and those books digitized in part by *Google Books* and the *Internet Archive*.

As one might expect, English is the main language of the archive. Roughly 3.9 million of their books, representing 49% of the unique holdings, are in English. The second largest represented group is German, followed by French, Spanish, Russian, Chinese, and Japanese. Given the large Spanish-speaking population in the United States, the small and disproportionate amount of Spanish-language materials is surprising. However, given that the audience is college students and faculty, German and French (second and third respectively) have long represented the cutting-edge of scholarship in more disciplines than Spanish. (HathiTrust, 2016) This will be discussed in greater detail below.-

HathiTrust is characterized by a robust search engine and extremely well-organized metadata and records management. Where *Google Books* has issues with the retrieval of specific dates and other types of metadata, *HathiTrust* performs information retrieval and document display with superior results. The system allows, however, only two types of views to the non-member user: 1) a limited view, which provides only search results to retrieve word counts from queries (i.e. full-text search), and 2) full-view, which provides the full text – but this is reserved primarily for materials in the public domain or those with specific author-provided permissions for open access.

Access is open to anyone able to use a computer connected to the Internet, but partnering institutions and their members benefit from extra services such as content storage, data preservation and copyright clearance/usage consultation. Although the current size of the collection is smaller in comparison to *Google Books*, the ability for one to find information more easily should make the *HathiTrust* the go-to MDL for *all* libraries and their patrons.

Internet Archive (10.1+ Million Texts)

The Internet Archive is also a unique addition to the Massive Digital Library category. On one hand their main focus appears to be on archiving the

Internet via its *Wayback Machine*. One of their stated goals, in fact, is to create archival artifacts of the web itself. This is important as the Internet may replace many of the print media sources available, including books. Unlike *Google Books* or *HathiTrust*, which focus heavily on collection sizes, *Internet Archive*'s primary concern has been less focused on the number of titles acquired. Instead, the *Internet Archive* gathers and approves only those materials in the public domain or that have author permissions. As a result, their print-derived digital collections are smaller but completely accessible.

Their advantage is also in providing links to several mass-digitization projects and allowing these projects to exist under their own names as well as within the Internet Archive web pages. Projects such as the *Biodiversity Heritage Library*, *Project Gutenberg*, the *Universal Library* and *Children's Library* are worthy open access book digitization initiatives aimed at providing people with free access to resources, all falling under the *Internet Archive* umbrella.

Their difference is also in one of scope, with their emphasis on audio recordings, video, electronic video gaming, and other unique multi-media collections. Additionally, the *Internet Archive* also provides access to about 9,500 audio recordings of books, including literature and poetry.

Other MDLs of Note

In recent years several other U.S.-based MDLs of significance have begun to appear. The most well-known of these, *The Digital Public Library of America* (DPLA) is also one of the newest. Due to aggressive partnership and digital hub development, its growth since October 2010 has been exceedingly quick. It currently holds nearly 14 million digital items, a huge increase from the 2.5 million at its initial launch. The collections specialize in a range of materials from books to digital archives. The scope ranges from materials for students and teachers at the K-12 level, and

for universities up to the graduate-student level. The main types of partnering institutions are broken down as follows: public libraries, 23.38%; university libraries, 22.19%; historical societies, 11.33%; museums 11.33%; archives, 7.50%. It is likely one of the major up-and-coming MDLs and has, it appears, learned from the experiences of its predecessors. (DPLA, 2014)

Additionally, the *California Digital Library* and *Texas Digital Library* continue to grow. Although they serve more localized, state-based interests, their open online accessibility ensures widespread impact. Many of CDL's digital book collections appear as subsets within Google Books, the HathiTrust, DPLA, and Internet Archive. (CDL, 2016) The Texas Digital Library's collections focus on large-scale institutional repository development and issues inherent to scholarly communication, especially ETDs, data management planning and archiving, digital preservation and digital objects. (TDL, 2016)

Non-Anglo-Centric MDLs of Note

Europeana (53+ Million Items / 3 Million Texts)

The *Europeana* digital library aggregates multi-media content from more than 130 institutions across Europe, including video, image, text and digital artifacts. It is a multi-lingual, multi-cultural endeavor. There appears not to be one dominant language in the project. With a huge collection of over 3 million texts the digital library should be considered a leading MDL in the field. Their emphasis on interoperability and a strong metadata schema allows users to refine searches and hone in on more relevant search results easily. The main focus for the library is to ensure that digital materials of numerous cultures remain freely accessible to all. The project advocates the strongest pro-Public Domain stance of nearly all the MDLs. It is a vital and important MDL as a result.

Gallica (2.5+ Million Items / 680 Thousand Texts)

Despite its relatively smaller book collection size, *Gallica* is noteworthy for several reasons. One, it is a primarily France-centric and Franco-phone Massive Digital Library. Its partners include many universities and museums in France but also the National Library of Brazil and the Library of Congress. There are books offered in English, but it is a small amount compared to other MDLs and dwarfed, obviously, by the size of the French language collection. *Gallica* is also, in many ways, an MDL counterpoint to *Google Books*, with a very different philosophy and approach to the digital library.

MDLs: MAJOR ISSUES AND CONTROVERSIES

MDLs, Mass Aggregation and the Accuracy and Veracity of Results

Google Books' policy for developing their Massive Digital Library appears to be very simple: *digitize everything*. Such ambition to collect all of the world's knowledge is not unheard of in the history of libraries, yet these are time-consuming and costly efforts requiring extreme amounts of funding and personnel to do them adequate justice. However, it is as ambitious as it is unrealistic. It is possible complete digitization may never happen as new books are still being published in print form yearly. Furthermore, not all books are available with digital counterparts or can even be scanned accurately and adequately. Some works made with high-quality materials, odd-sized or hand-crafted paper, or three-dimensional forms are preferable to many readers as solid objects and not as two-dimensional digital copies. Some countries such as Japan have traditional binding procedures that are unique and not easily transferable to digital formats.

The estimation of 129 million books may also be flawed. Relying on ISBN numbers is not accurate as many countries did not adopt ISBNs until the 1960s or 1970s. The differentiation between serials, multi-volume works, multiple editions and the concept of "books" is unclear as well. Does Google consider the 51 volumes of the Harvard classics as one book, with one record as in a library catalog or the HathiTrust, or are they 51 books? Does the second edition of volume 13 of the Harvard Classics really warrant digitization if the first edition is available? A "digitize everything" approach does not suitably answer these questions and an assumption of universality becomes a disservice to all.

Endeavoring to digitize all the books is not so much a collection policy as it is an avoidance of one on a massive scale. The results are akin to a typical Google keyword search: a mixture of high and low culture with only relevance ranking, which can be manipulated by both black and white hat Search Engine Optimization (SEO), to determine whether it is a satisfactory result. One concrete example of this issue has been the inability for the Google Books search engine to accurately retrieve and coherently display single works of multiple volumes. A search of the Harvard Classics results in a jumbled non-sequential retrieval of titles. Unless one had known before-hand that *Harvard Classics* contains 51 volumes, one might never get an accurate accounting of the texts from Google's set result.

At the same time, digitizing all content will also include books of questionable natures, including the literatures of hate, pornography, and other provocative or even dangerous materials. Yet, despite their intention to digitize everything, it is unclear due to Google's secrecy whether they have digitized materials that are hateful or offensive to various groups.

One must be wary of this approach as well, because not only will books be missed - especially those not held by Google's Partners - but also a lot of unnecessary, spurious, or poorly written

materials will be added to the collection. This in turn dilutes the rationale for collecting something.

Additionally, the accuracy of the metadata needed to track and provide information retrieval in meaningful human-readable ways is also at risk. James and Weiss (2012) found a high rate (36%) of errors in their study of Google Books' metadata. Other scholars have been pointing out the "train wreck" that is Google Books' metadata for quite some time. (Duguid, 2007; Nunberg, 2009;)

Weiss and James have also examined rates of error among metadata and in scanning results. James (2010), Weiss and James (2013a, 2013b, 2014, 2015), and Weiss (2016) have found significant evidence of errors in Google books.

All of these issues, from responsible collection and content aggregation to the accurate retrieval of information, including both reputable and appropriate sources as well as accurate information for specific bibliographic units, are intertwined. Accuracy and veracity of the content goes with its ability to be perceived as trustworthy by the MDL's users.

MDLs and Copyright

It would be an understatement to say that MDLs have had some impact on copyright law. MDLs can be seen as logical extensions of the Internet's early promise of the information superhighway and the democratization of knowledge. Yet there has been intense backlash from all sides against MDLs. Indeed, the two largest of the Massive Digital Libraries, HathiTrust and *Google Books*, were saddled with high-profile lawsuits, both initiated by the Author's Guild, from the mid-2000s until recently.

By November, 2013, Google's long legal fight eased somewhat with the ruling in Google's favor by Judge Denny Chin. (Lee, 2013; Chant 2013) By 2014 appeals were also found in favor of the HathiTrust over the Authors Guild. (Chant 2014) By April 2016 Google's case had been resolved with the United States Second Circuit ruling in fall 2015 in favor of the tech giant, and the U.S.

Supreme Court declining to examine the case further. (Hurley, 2016)

Looking at it more objectively, though, Google's problems stemmed from the proprietary nature of their endeavor. If they were to abandon some of the profiteering or perhaps alter the purpose of their program, it might have been seen in a better light by the Authors Guild. Despite Google's controversial approach, however, the U.S. Supreme Court considered the project to be within the guidelines of fair use, especially regarding the ultimately transformative use of the source material. (Hurley)

HathiTrust, in contrast, weathered the copyright lawsuit storm quite well and remains poised to develop as the leader of MDLs in terms of copyright compliance and providing accessibility to the disabled and access to public domain works. The result of their lawsuit showed that the Fair Use defense remains a strong one as long as it is coupled with such factors as restricting access to copyrighted work and remaining non-profit in nature. Their digitized corpus was also ruled Fair Use because of the importance the *HathiTrust* placed upon providing works with greater accessibility for the disabled. The Fair Use defense also made it clear that the *scope* of a project, which the Author's Guild had criticized, is irrelevant. Fair Use holds, regardless of the number of books digitized.

Among other MDLs, *Europeana's* efforts in advocating for a strong and robust public domain make it a worthy cause to follow. (Fallon) It is hoped by the author that they continue to fight for strong and clear open access of cultural content disambiguated from the profit motives of the corporations that tend to own the lion's share of copyrighted material.

The Promises and Pitfalls of Diversity

Google Books' partners have included institutions in Spain, Germany, France, and one university in Japan. (Given the huge number of books, languages and cultures in the world, one must consider deeply

whether such limited partnerships are feasible and scalable. In order to have complete universal coverage, one would need to add partners from everywhere, including institutions devoted to sub-communities and sub-cultures within larger countries. But despite such ambitions to create a digital corpus of everything printed, it is likely not a realistic outcome.

Furthermore, the act of scanning itself causes distinct issues. As Thylstrup writes, once a decision is made to digitize content, scanning becomes a political act rife with “distinct subpolitical processes.” (2014) In addition, researchers have found that the contents of the Google Book corpus do not represent an unbiased sampling. Pechenick et al. argue that “the evolution of the corpus throughout the 1900s is increasingly dominated by scientific publications rather than popular works. We have shown that even the first data set specifically labeled as fiction appears to be saturated with medical literature.” (2015) Aside from the problem of misrepresenting common collections, or transforming the boundaries of traditional print forms, the selection of texts appears to be skewed in favor of scientific titles. Weiss and James find missing public domain books in the Google corpus and a low representation of Spanish and Japanese language texts. (2013b, 2015) The diversity of content in the *Google Books* project as well as any of the other MDLs, therefore, remains at the mercy of the partnerships they have created.

For the *HathiTrust*, similar issues exist. The number of partners is large, but still not comprehensive. According to their online statistics, the percentage of English language books remains at about 50%. Of the top ten languages, 60% are Indo-European, with one, Latin, being a dead language. Two are East-Asian Languages (Chinese / Japanese) and one is a Slavic language (Russian). (HathiTrust, 2016) By world population and the number of cultural artifact created by various cultures – especially those that are older than the United States by millennia – the collections are disproportionately skewed toward the English language. Again, like the *Google Books* project

-- and in part because many of the *HathiTrust* partners as well as digitized books are shared with *Google Books*--the issue of the source materials calls into question the ability of MDLs to create diverse collections.

For Public Domain works, this proportion skews even further to English - about 60 percent of titles in the public domain are English with 40 percent left for any other language. Generally, this reflects the needs of the faculty and students at the academic institutions currently partnering with the *HathiTrust*. It is quite telling that the second and third largest collections of works are German and French, while Spanish, the second most-spoken language in the United States, trails at a distant 4th. Only 4.48% of the HathiTrust online collection is in Spanish, yet 36 million people (roughly 12% of the population) in the United States speak Spanish as their primary language. In contrast, only about 1.3 million (or.41%) speak French and only about 1.1 million (about.35%) speak German, yet the HathiTrust collections include 7% and 9.2% of these languages respectively. (US Census Bureau, 2011)

It is clear, then, that subject matter diversity could be better addressed by even the MDL exemplars. It is hoped that as these digital libraries develop over time, the gaps found in their coverage will adapt to the new, at-large audiences that exist beyond the physical boundaries of the locations they represent.

FUTURE RESEARCH DIRECTIONS: IMPACT OF THE DIGITIZED BOOK CORPUS

Humanities and the Ngram Viewer

One important impact that MDLs can have on current scholarship is the mining of the immense data sets generated from the mass digitization process. The Ngram viewer, designed by John Orwant and Will Brockman at Google, provides data visualizations for the frequency of queried

terms. This is a helpful tool for not only historians, writers, artists, and social scientists, but also libraries. (Google N-gram, 2016) Michel, et al. (2011) have shown the impact that research in this area, which they have called “Culturonomics,” can have on scholarship and textual analysis. Additionally, one can track historical events in the news or the ideas and concepts that accompany them. It is truly a useful tool for those interested in the history of ideas and how events shape them.

In the example shown in the figure above, a search involving the terms <Hiroshima> (in blue) and <Nagasaki> (in red) was conducted by the author. The search results show the frequency with which the words appeared in the English language from the period of time from 1800 to 2000. For the first 140 years, Nagasaki was the more mentioned of the two cities, likely a result of it being the only port open to foreign trade during the closed-country *sakoku* period in Japan. During the 1850s-1860s, Nagasaki also began to surge, likely a result of the United States’ aggressive policies to “open” up the country to international trade. Again a surge occurred between 1900 and 1910, reflecting its status as a major hub for coal

production and the Japanese Navy’s winter port for the Russian Asiatic fleet.

Hiroshima during this same period of time is not mentioned very much in comparison, trailing at a very distant second. However, during the years after the bombing of Pearl Harbor, Hiroshima becomes ever more frequently mentioned. Only by 1944, a year prior to the atomic bombings of both cities, do Hiroshima and Nagasaki reach parity in terms of frequency. After 1945 until the present day as a result of being the first city to suffer an atomic bomb attack, Hiroshima has been mentioned the most.

It is a useful tool for students to get a better sense of the context of historical events and an understanding of how notoriety waxes and wanes over time. It becomes clear then that MDLs can offer more than just digital versions of books and get at assisting not only scholars but also interested lay-persons, librarians, and students. The ability to search for concepts across a large sample of materials will revolutionize the humanities, the history of science, and even science itself, as people begin to see the patterns in knowledge development and information retrieval.

Figure 1. Ngram viewer showing frequency of the names Hiroshima (blue) and Nagasaki (red) from 1800 to 2000. Note the significant change starting in the early 1940s and spiking post-WWII

CONCLUSION

The Massive Digital Libraries covered in this chapter (*Google Books*, *HathiTrust*, *Internet Archive*, *Europeana*, *Gallica*) show striking individuality in their approaches to mass-digitization and the mass-distribution of digitized content. Yet many of their defining characteristics—from size to content aggregation, to development of consortiums and to content diversity and general accessibility—remain nonetheless similar. Their central missions to share the content of print books that may be locked away in print on physical book shelves are also admirable. Varying degrees of scope, subject matter and audience involvement shape these massive collections in individual ways, making each MDL unique.

Overall when looking at the main examples of MDLs currently in existence, one gets the sense that ambitions for a “unified digital front” for all types of materials is the impetus driving their development. This ambition impacts brick-and-mortar libraries in that they may have to scramble to accommodate as well as take advantage of these growing initiatives.

The issues raised by MDLs speak directly to the issues at the heart of mass-digitization culture. Veracity, accuracy and diversity get at the essential quality of any information society: trustworthiness. If one is able to trust the mass aggregated collections, then MDLs will provide an essential service to the pluralistic and digitally democratic societies from which they have sprung. Additionally, the issues of copyright are providing a lesson to all on Fair Use and the development of new open access/open source culture dependent upon the alteration and recombination of previously created works. The new tools and applications of MDLs, such as the Ngram Viewer, despite some of the issues of representation existing at the heart of the Google Books corpus, promise to surpass the individual books in the MDLs’ corpuses. MDLs will ultimately provide users with enhanced approaches to existing disciplines as well as the promise of new transformations.

KEY TERMS AND DEFINITIONS

Digital Corpus: The full-text of millions of books digitized by the MDLs. These provide opportunities for scholars to examine the frequency of terms as they appear in the print corpus.

Digital Humanities (DH): A branch of the humanities incorporating digital search, digitized texts, encoding, and other strategies to move previously print-bound materials and scholarship into computer science related analysis.

Fair Use: Defined by some as the breathing room to allow for the freedom of expression, it is a strong limitation of the extent of copyright law. It is determined by examining four factors: 1) the purpose and character of the use; 2) the nature of the copyrighted work; 3) the amount

and substantiality of the portion taken; and 4) the effect of the use upon the potential market.

Mass-Digitization: The practice of quickly and thoroughly digitizing items on a large scale. In the case of MDLs these efforts involve scanning millions of books with multiple institutional partners across national boundaries.

Massive Digital Libraries (MDLs): Term adopted to describe the mass-digitization of printed books and the mass-aggregation of their metadata into online, full-text-searchable digital collections; some component of open access and use of public domain works defines their collections; diffuse and diverse target end-user groups are also characteristic of MDLs.

Ngram Viewer: A tool developed by Google to aid in the visualization of the digital corpus of books. It plots frequencies of terms across a graph, helping users understand how common a word or concept was in the corpus at a specific moment in history.

Public Domain: Works that are no longer under copyright protection. In the United States these works tend to be those published before January 1, 1923 and unpublished works created prior to 1893. U.S. Government publications are public domain.

Mission, Tools, and Ongoing Developments in the So.Re.Com. “A.S. de Rosa” @-library

Annamaria Silvana de Rosa
Sapienza University of Rome, Italy

INTRODUCTION

Knowledge Domain

Originated from Serge Moscovici's¹ *Opera Prima* (1961), Social Representations theory (S.R.), originally European, is currently a multilingual worldwide field with a substantial body of literature in social psychology and other social science. Studies of “what” people know – and “how” this lay people knowledge relates to the social groups to which they belong and are shaped by the polyphonic traditional and new media system – are concerned with the social construction of everyday knowledge and the related socially situated practices. The “objects” studied have a strong societal impact in the social spheres.

This *supra-disciplinary field* is characterized by a *great consistency in terms of epistemological and theoretical inspiration* and a rich diversity both:

- From the *paradigmatic point of view* (“structural,” “social positioning,” “monographic,” “anthropological,” “dialogical,” “modelling” approaches);
- In terms of *methodological research designs* (qualitative, monographic, anthropological, experimental, descriptive, structural, visual-figurative, multi-methodological, etc.);
- From the *thematic point of view*
- With respect to the *applied contexts and domains of expert and lay knowledge*

production and transmission: education, health, economics, environment, tourism, politics, organizations, media industry, etc.

The goal of this contribution is to present background, mission, ongoing developments and future research directions of the *So.Re.Com. “A.S. de Rosa” @-library: a digital platform integrating scientific documentation, networking and training purposes* in the field of *Social Representations and Communication* (So.Re.Com.).

BACKGROUND

Born from a personal bibliographic inventory, initially including almost 500 references in the field of *Social Representations and Communication*, the *So.Re.Com. “A.S. de Rosa” @-library* (de Rosa, 2015c) has been transferred into an ad-hoc designed relational database implemented in 1996 on the *European/International Joint PhD in Social Representations and Communication* website (de Rosa, 2000, 2001, 2004 a, 2004 b, 2006; 2008, 2009 a, 2009 b, 2010 a, 2010 b, 2010 c; 2011, 2014, 2015a, 2015b, 2015c, 2016a; de Rosa & Picone, 2007).

It is built on an on-going multi-year project aimed at an *empirical meta-theoretical analysis of the whole literature on Social Representations* (de Rosa, 2013a, 2013b, 2016b; de Rosa, Dryjanska, Bocci, 2017a, 2017b). Guided by the main goal of *evaluating the impact of the scientific production driven by the Social Representations theory in the*

social arena faced with social demand, the aim is to take stock of the scientific field developed in more than 50 years by conducting an empirical meta-theoretical analysis of the literature on Social Representations, mapping the development of different paradigms, the related research methods, the thematic areas and their impact on the various applied fields within the multi-generational community of scientists and across different geo-cultural contexts. This research program is led by de Rosa, creator and program director of both the *European/International Joint PhD in S.R. & C.* (<http://www.europhd.eu>) and the *So.Re.Com. THEmatic NETwork* (<http://www.europhd.eu/SoReComTHEmaticNETwork>), a *network of networks* that promotes co-operation between academic, professional research and commercial institutions and facilitates the dissemination of scientific results in the field of Social Representations (see Figures 1 and 2).

Located at Sapienza University of Rome Sapienza - the largest university in Europe with a patrimony of 155 libraries and a recent investment in digitalising contents² - the state-of-the-art of the *Social Representations and Communication Research Centre and Multimedia Lab* includes the

integrated specialized physical and *So.Re.Com. “A.S. de Rosa” @-Library*. It is the nerve centre of the *European/International Joint PhD programme in Social Representations and Communication*, the training structure of the wider *So.Re.Com. THEmatic NETwork*, dedicated to research and training needs for both doctoral candidates and highly experienced researchers, individually or in cross-national research teams.

Recently (2012) transferred from its historical location opposite Campidoglio to another larger location in the very heart of Rome at the top of Aventino hill, overlooking the capital’ archaeological-architectonic center, it guarantees technical support for training and management activities, including real-time interactive exchanges with partner institutions around the globe.

Full-time staff is available to provide assistance to users.

MISSION

A research environment “*based on*” and “*aimed at*” integrating *scientific documentation, networking and training purposes*.

Figure 1. The So.Re.Com. Joint Innovative Doctoral Program institutional network

Figure 2. The So.Re.Com. THEmatic NETwork at a glance on global scenario

The So.Re.Com. “A.S. de Rosa” @-library is a multipurpose digital environment of interrelated relational databases conceived in the logic of the semantic web, including multiple web interfaces aimed to integrate *documentation services*, with *networking* and *research training*.

Once the ongoing migration into an open access platform will be completed, the So.Re.Com. “A.S. de Rosa” @-library will answer the increasing demand for multi-lingual access to multi-format documentation in Social Representations and Communication, also from users in disadvantaged areas in the world where information and training are difficult to obtain. The ultimate goal is to make it accessible to anyone, anytime, anywhere, therefore disseminating resources otherwise dispersed and fragmented in several universities, public and private research centers and governmental institutions.

To accomplish these goals, its creator and project leader is coordinating a large team of human resources with different degree of expertise since many years, in order to produce, collect and meta-analyze scientific documentation published in the field all over the world, not exclusively by the So.Re.Com. Thematic Network members.

This @-library supports access to multiple repositories and web-tools, designed by A.S. de Rosa and implemented on the EuroPhD website, in order to integrate the three main pillars (Figures 3, 4, and 5).

Documentation

- A *comprehensive bibliographical repository* of the literature on Social Representations, currently including more than 10000 references. This growing collection of bibliographic entries includes not only the classic bibliographic details, but also the author's and co-authors Institution affiliation and Country/Continent, the bibliometric indexes (Impact Factor and SJR) and other useful information for geo-mapping the diffusion and impact of the theory over the world, by decades and thematic areas and for visualizing the intra and inter-institutional authors' collaborations by city, countries, continents.
- A *meta-theoretical analyzed repository* of the literature on SR, currently including more than 4000 meta-analyzed articles or

Figure 3. The So.Re.Com. “A.S. de Rosa” bibliographical repositories and @-Library

book chapters using the on-line grid for the “meta-theoretical analyses” and the guidelines developed by A.S. de Rosa (1994, last version updated January 2014).

- An *intelligent @-Library* holding a rich documentation of almost 10000 PDF texts, videos, audio-interviews and multi-media scientific and training materials in the field of S.R.
- Advanced search engines hyper-linked with all the three above-mentioned repositories (also using as ontologies the categories of the very detailed “meta-theoretical analysis” grid) and for the full text search on the PDFs.

Networking

- More than 3000 members of the worldwide *SoReCom Thematic Network* on-line community, including personal and institutional information and scientific profiles.
- News and calendar of scientific events.
- Online co-operative research tools.
- On-line web-conference management system for participant registration, submission and review of abstracts, power point presentations and papers, interactive feedback system for editing and publishing.
- SoReCom THEmatic NETwork @-NEWS.

- Newly designed management service for “*Virtual meetings with authors or book presentations*”.

Research Training

- Multi-point web-videoconference interactive system, also sharing applications and files.
- Developing research trainees’ skills in meta-theoretical analysis of S.R. literature and advanced use of bibliographic *repositories*.
- Distance tutoring and co-tutoring based on personalised access to research reports and on-line evaluation of trainees’ research reports at the initial, intermediate and final stages.
- Video-lectures in streaming and web-video-interviews with the protagonists in the scientific field.
- Web-tools allowing research trainees and professors to provide “ratings,” i.e. feedback on the virtual training activities and those involving physical mobility, etc.
- Dynamic timeline for research training activities management and credit accumulation sheet.
- Personalised inventory from the application to the degree and beyond.
- Alumni community and career development.

Figure 4. @-learning Kit at disposal of the So.Re.Com. European/International Joint Ph.D. research trainees

@-learning Kit

The complex package of multimedia tools to be developed and disseminated via Internet includes:

- a full bibliographic inventory
- a meta-analyzed inventory
- an advanced search engine
- a specialized e-library in SR & C.
- digitalized studio produced videos
- magisterial lectures produced in real time (videoconferences)
- on-line interviews with leading experts
- European Ph.D. web-auditorium
- on-line workshops among participants and academics
- a "virtual campus" SR & C scientific community online database.

Figure 5. Distance tutoring and co-tutoring tools based on personalised access to research reports and on-line evaluation of trainees' research reports

Quality Control and On-Line Monitoring System

Assessment tools used in the Open distance learning system are of fundamental assistance in continuously monitoring the quality of training.

The quality of the scientific and didactic content is evaluated by the Program Director in co-operation with the the tutors. This is accomplished using evaluative tools and co-tutoring, including distance co-tutoring that continuously monitors the student training via the European doctorate's dedicated web site.

After monitoring the work of previous years, among the other quality control procedures, the Core Executive Committee decided to impose a more structured "time constraint" on the development of early stage researcher's programs.

This offers tutors on-line evaluation tools for various versions of the research trainees' projects:

- ♣ Initial short version
- ♣ Intermediate extended version
- ♣ Final full report and short version

These tools have been installed in the web site for every registered research trainee <http://www.europhd.net>. They are considered confidential and, by using a password, are accessible for consultation only by the didactic triad of the 3 tutors (1 national + 2 foreign tutors), the Programme Director and the research trainee him or herself.

In addition, the procedures for presentation and evaluation of dissertations before the Final Jury have been organized, structured and appropriately tested in the course of the first dissertation defenses.

RESEARCH DIRECTIONS: THE FUTURE IS ONGOING!

Coherently with the planned developments (see de Rosa, 2015b) *from the content point of view*, we are pursuing the envisaged progress:

- An increased critical mass of content and related metadata of the *So.Re.Com. "A.S. de Rosa" @-library* by 2017 - thanks to the approval by the European Commission of the 2013-2017 contract *SoReComJoint-IDP* People-Innovative Doctoral Program positioned at the highest ranked (98,80/100 mark) among 1175 proposals. Built on the sound experience of both the *European/International Joint PhD in Social Representations and Communication*, approved by the EC since 1992, and the *So.Re.Com. THEmatic NETwork*, the *SoReComJoint-IDP* project is coordinated by Sapienza University of Rome and includes 13 universities, 2 private companies, 1 national research centers with cooperation with private sector in 8 European and 6 extra-European countries (Austria, Czech Republic, France, Italy, Romania, Spain, Sweden, Switzerland, Argentina, Brazil, Canada, China, Mexico, United States). This large and diversified network ensures a wide range of complementary paradigmatic, methodological and thematic options offered by international and cross-sectorial research teams within and outside European borders. The associate partners perform vital tasks such as co-tutoring activities, hosting Early Stage Researchers (ESR) for secondments and providing valuable training modules during the project's foreseen scientific events.
- The *So.Re.Com.Joint-IDP* will contribute to disseminating also the meta-theoretical knowledge produced by a new team of 13 ESR – recruited in 2014 - who will continue to work together until 2017, by mediated access to the best comprehen-

sive specialized @-library worldwide, on the on-going multi-faceted project led by prof. A.S. de Rosa (the *European PhD Lab* director) on top of previous multiyear work carried out with the long term purpose of writing a *Biography of the Social Representations Theory*. This unified research project framework has been articulated into 13 precise objectives concerning the specific research lines to be developed by each recruited ESR, matching their own interests and area of prior expertise. The ESR cooperate in meta-theoretical analyses and contribute to the development of the specialized *So.Re.Com. "A.S. de Rosa" @-library*. The integrated research framework provide an integrated training opportunity to maximize the cooperative and joint expertise of both the host institution and associated partners, doing so from the theoretical, methodological and applied perspective of the researches conducted in more than 50-year development and diffusion of this scientific field, with a view to monitoring and exploiting its added value to respond to social demand in the multiple contexts of the social arena: from economics to the environment, politics, health and community issues, science communication, etc. The need for developing both core and wider employment related skills is driven by the goal of making research training of greater relevance for a wider variety of careers both in and outside academia, internationally and globally more attractive.

- Driven by the synergic goal of an integrated development of the documentation tool "of" and "for" other researches (*So.Re.Com. "A.S. de Rosa" @-library*) and the training activities of the International doctoral program - among other multi-year series of activities, the *Winter Session International Lab Meeting* are specifically aimed at training in the *meta-theoretical analysis* of the specialized literature on

S.R.: why and how to map the development of different paradigms, the related research methods, the thematic areas, their impact on the various applied fields and the new emerging research directions within the multi-generational community of scientists and across different geo-cultural contexts (http://www.europhd.eu/html_onda02/07/28.01.00.00.shtml). The program includes:

- *Key lecture* by the research leader, aimed at presenting the current status of the Meta-Theoretical analysis of complete body of the S.R. literature.
 - *Presentations by So.Re.Com. Joint-IDP expert post-docs* and advanced doctoral trainees involving a *multi-generational community of senior and junior scientists* that ranges from visiting post-docs to Euro PhD Alumni (including former Marie Curie Fellows), already well trained in the *meta-theoretical analysis* of the specialized literature on Social Representations.
 - *Training the ESR* for developing advanced bibliographic on-line search skills via access to other digital libraries, aimed at developing the large specialized full bibliographic *repository* and the *So.Re.Com. "A.S. de Rosa" @-library*.
 - *Presenting guidelines* for integrating bibliographic resources in the physical and digital SoReCom specialized libraries.
 - *Training the ESR in the meta-theoretical analysis grid* and tools of the meta-theoretical analysis *repository* including the following tasks and methodology. Following guidelines and procedures given by the project leader prof. A.S. de Rosa and a specific training, the specific ESR's contribution consist:
- To detect and retrieve publications not yet inserted in the So.Re.Com. "A.S. de Rosa" @-Library, and meta-analyze the whole body of the literature on Social Representations produced according to the "specific individual research focus" over the world and not only in the geo-cultural context/continent of the host institution for mobility stage;
 - To fill new information and upload the related PDF files into the specialized So.Re.Com. "A.S.de Rosa" @-Library;
 - To carry out statistical analyses on the complete meta-analysed body (extracted from the SoReCom "A.S. de Rosa" @-Library after the integration of the new information);
 - To produce video-interviews – according to an outline designed by the project leader - with the key scientists who contribute to the development of the paradigmatic approaches to Social Representations;
 - To fully describe, comment and visualize the results using de Rosa's Guidelines for the geo-cultural mapping in the PhD thesis in English (in the book format and short article).
- Illustration of the *double quality control system*.
 - *Co-ordination and planning session* for the organization of weekly individual and group ESR small meetings on the transversal common tools of the overall research program and the specific goals of each of the research focuses.

- The complementary training stages at 13 host institutions in Europe (Austria, Czech Republic, France, Romania, Spain, Switzerland), in North and Latino America (Canada, Argentina, Brazil, Mexico) and in China, from September 1 to November 30 2015, has also offered the ESR opportunities for networking with the associated partners and for further integrating virtual and physical international mobility.
- The supra-disciplinary, multi-methodological and thematic possibilities offered by the training network are enhanced the wide range of world-class visiting researchers invited to participate in the program’s intensive training “stages,” multi-point videoconferences, tutoring and co-tutoring for individuals and small groups, and various on-line training tools.

Also the planned developments *from the technical point of view*, are currently ongoing as envisaged:

1. Ongoing transfer into a new web-platform from *web-object* to *Drupal*, expanding access via new web interfaces (see Figures 6 and 7).
2. To implement a management service innovation enabling users to *virtually meet authors of the @-Library’s content by jointly coordinated on demand meetings* between early stage researchers and famous authors belonging to the SoReCom scientific community.
3. To pursue future integration in the larger Sapienza Digital Library and in the European Digital Library, improving accessibility, use and dissemination, while keeping our autonomy in the content management and quality control system to update data and meta-data.

Figure 6. The new home page of the European/International Joint-PhD in Social Representations and Communication

Figure 7. The new web interface of the Basic Search for the bibliographical repository of the So.Re.Com. “A.S. de Rosa” @-library

Therefore the developments of the *So.Re.Com. “A.S. de Rosa” @-library* from the content and technical point of views – supported by the approval of the SoReCom IDP People project – has facilitated by and will contribute to improve interaction among the three pillars of the *European/International Joint PhD in Social Representations and Communication Research Centre and Multimedia Lab*: documentation, training activities and networking.

CONCLUSION

The unique combination of a *European/International Joint doctoral program and a scientific network including academic and extra-academic partners* – once again approved by the European Commission as the top project 2013 People Innovative Doctoral Programs (*So.Re.Com.Joint-IDP*) – is an integrated physical and virtual campus

where initial research trainees and experts from academia and the public and private sectors can come together to learn, share, create and disseminate knowledge. We offer a progressive system for training early stage researchers through active research. Research training takes place in international environments, both academic and non-academic, with specifically designed intensive didactic “stages” in multilingual and multicultural settings. This includes access to the specialized physical and @-library in Social Representations (the *So.Re.Com. “A.S. de Rosa” @-library*), meta-theoretical analysis of the literature on Social Representations and Communication, tutoring and co-tutoring for research projects, active participation in International Lab meetings and International Summer Schools, advanced training in multi-methodological qualitative and quantitative design, software for statistical data analysis and results visualization, e-learning activities via interactive video-conferences, training in comple-

mentary skills, scientific networking, and active participation in international conferences, etc.

This integrated face-to-face and open virtual space, accessible from anywhere in Europe or the world, not only meet the needs of its users by providing easy access to publications and meta-data and many other kinds of digital multi-format documentation (printed, pictures, audio-videos), but also enables them to quickly become content providers and co-producers. The multigenerational nature of this interactive knowledge community guarantees cross-fertilization of ideas between senior scientists and early research trainees, as well as between experts from within and outside of academic circles, including policy makers interested in research on societal issues and their relevance in social contexts. Therefore, open access to the integrated physical and virtual *SoReCom THEmatic NETWORK* infrastructure will allow the members of this knowledge community to continue to grow. The newly designed web-services for enlarging interactive facilities of the *So.Re.Com. "A.S. de Rosa" @-library* not only gives research trainees access to documentation, but in the physical and virtual space of this infrastructure also they can also meet authors and each other to discuss new publications and critical research areas.

In conclusion the *So.Re.Com. "A.S. de Rosa" @-library* provides *an integrated digital tool for scientific documentation, networking and training purposes in the supra-disciplinary field of Social Representations and Communication*, thus stimulating a rich and ever-growing research and learning environment that is advantageous to research team members, trainees and experts alike.

Comparative analyses - aimed at answering to research questions related to the worldwide dissemination of the Social Representations and its positioning compared other theories and approaches of social sciences – can be based on almost “big data” and “meta-data”, filed in our *SoReCom "A.S. de Rosa" @-library* repositories. In fact this is the most comprehensive library specialised in Social Representation, compared to the universe of the total literature of this scientific

field. Therefore we may define our data sources as almost “big data”, if we assume that “There is no one definition of Big Data. Thought about in simple terms, Big Data involves datasets that are far larger than those traditionally examined in journals like this one. Yet there has always been considerable variation in the size of datasets, ranging from small experimental studies to large samples involving census or polling data. Size alone is therefore an insufficient descriptor” (Parks, 2014, 255).

Just to make an example, in order to examine the bibliometric impact of the literature inspired by the Social Representation theory compared to its global dissemination, we have used data concerning authors’ countries and institutional affiliations, the bibliometric indexes (Impact Factor and SJR), the language of the publications, the thematic choice, the networks of inter-institutional collaboration within and between countries and continents (in order to detect who is working with whom on what and in which country...), etc. The implications of the “*impact of the impact*” has been discussed in other publications in the light of the critical debate, which still animates the community of scientists, stimulating meta-reflexive discussion and view exchanges among the members of our scientific community on the preferable publishing options and collaborative strategies in the current editorial and academic scenario (de Rosa, A.S. 2015c, de Rosa, A.S. Dryjanska, L. Bocci, E. 2015, in press). These publications also illustrate an example of the prototypical use of the *SoReCom "A.S. de Rosa" @-library* as a *research tool*, rather than simply an *online repository for scientific documentation*, so accomplishing one of its mission.

KEY TERMS AND DEFINITIONS

European/International Joint PhD in Social Representations and Communication and So.Re.Com. Joint-IDP: Built on the experience of both the European PhD on Social Representations and Communication, awarding a recognized joint degree since 1996 (<http://www.europhd.eu>), and the EU approved So.Re.Com. THEMATIC NETWORK, this international joint doctoral programme, co-ordinated by Sapienza University of Rome (Italy), includes 8 universities, 2 private companies and 1 public research institute in 8 European countries (AT, CH, CZ, ES, FR, IT, RO, SE) and 6 universities in United States, Canada,

Brazil, Argentina, Mexico and China. The goal is to provide doctoral training in Social Representations and Communication, a supra-disciplinary research area of the social sciences that studies the social construction of everyday knowledge in social spheres and media, disseminating European excellence beyond the EU boundaries and attracting the best Early Stage Researchers from abroad. Structured into transnational teams by common research area and complementary multi-methodological approaches, this So.Re.Com.Joint-IDP guarantees a well-tested training structure including: a) an innovative integrated physical and virtual campus, where world-class academic scientists, internationally recognized experts, experienced researchers and ESR cooperate face-to face and online “for” and “by” research; b) multiple supervision via tutoring and co-tutoring by at least three tutors in different countries; c) individual mobility for ESR at research centers for secondments; d) collective international mobility of trainees and teaching staff during International Summer Schools and Lab meetings; e) learning by doing (including transferable skills) in academic and non-academic settings; f) worldwide access to common web platform, as tool for documentation, networking, training and monitoring trainees’ progress; g) high tech infrastructure and lab facilities; h) quality evaluation system; i) officialisation of the joint degree; l) active integration in the world-wide SoReCom THEmatic NETwork; m) enhancement of career prospects both in and outside academia.

Social Representations: Social Representations and Communication is a supra-disciplinary area of the social sciences, representing a unifying meta-theoretical perspective, in particular from the optic of Social Psychology, inspired by the Social Representations Theory, one of the most important theories of the social construction of knowledge and its relation to socially situated

practices, founded by Serge Moscovici in 1961. This supra-disciplinary field is characterized by a great consistency in terms of epistemological and theoretical inspiration and its rich diversity both from the paradigmatic point of view, in terms of methodological approaches, from the thematic point perspective and with respect to the applied contexts and domains of expert and lay knowledge production and transmission: education, health, economics, environment, tourism, politics, organizations, media industry, etc.

So.Re.Com. “A.S. de Rosa” @-library: The So.Re.Com. “A.S. de Rosa” @-library is a multi-form digital environment of integrated relational repositories conceived in the logic of the semantic web, including a series of web interfaces aimed to integrate documentation services (bibliographic repository, meta-theoretical analysis repository, intelligent @-Library) with networking (interactive web-videoconference, on-line So.Re.Com. virtual community) and research training (European/International Joint PhD “Virtual Campus”: video-courses in streaming, distant tutoring and co-tutoring, on-line trainee evaluation, timeline management, etc.).

Social Media Applications as Effective Service Delivery Tools for Librarians

Ihuoma Sandra Babatope

Delta State College of Physical Education, Nigeria

INTRODUCTION

Social networking refers to a process of relationship building among a group with a common interest (Suraweera, Kahingala, Batepola, Punchihewa, Senevirathne and Kahandwaarachchi, 2011). The use of social media for information communication, information sharing, for pleasure, for dating, work related purposes and so on, is growing rapidly, therefore, their importance in academic libraries cannot be over emphasized. Academic libraries are libraries established in higher institutions (universities, polytechnics and colleges of education) by their parent institutions for the primary purpose of teaching, learning and research which therefore forms an integral part of the institution's educational system.. With the exponential growth of the use of social media such as the Facebook, Friendster, MySpace, Flickr, Instagram, LinkedIn YouTube, Twitter, Blogs, Wikis, Delicious, Online groups/forums,, Library Thing, Ning and so on, it has also become inevitable that academic librarians around the world and especially in Nigeria, must learn to use these tools to be able to keep their ever growing and sophisticated patrons and also remain relevant in the society.

Adeleye (2015) noted that these sites can be oriented towards work-related contexts (LinkedIn.com), romantic relationship initiation (Friendster.com), connecting those with shared interests such as music or politics (MySpace.com, Twitter), or the undergraduates population (Facebook.com). Social media such as Facebook was used initially for social discussions, over time it evolved into

the grouping of individuals into specific groups. Professional groups started to spring up and within time the library profession had its own group with the sole purpose of sharing ideas and gathering first hand information regarding the profession.

Beyond this, the different academic libraries in the country have felt the need to move with the times. The emergence of social media in academic libraries has changed the way information is delivered to the library patrons. Libraries have started to use these tools to interact with their patrons on real time. In fact, given the present economic scenario in Nigeria, where library budgets have been constantly on the decline, the social media have become a means for serving our patrons in a more specialized, interactive, and value added way without incurring undue expenses.

Hence, it has become very important for academic libraries to embrace these social media for effective service delivery to their library users and also to improve the library profession tremendously in Nigeria. Also, the previous top-bottom approach to service delivery where the library would pass information down to its patron without feedback will no longer suffice for our ever growing clients. Library users have been yearning to be a part of the services rendered to them, in essence being able to dictate what they need thereby making for a more interactive service delivery which will foster a two way communication pathway and provide the opportunity for more involvement. Undoubtedly, Nigeria which is still suffering from dwindling economy, are faced with diverse challenges amidst the opportunities derived from the intrusion of social media.

Consequently, a gap exists in literatures on the intrusion of social media in academic libraries in Nigeria. Hence, this chapter sought to bridge this gap by investigating the intrusion of social media in academic libraries in Nigeria as well as their opportunities and challenges for effective service delivery to their library users. Therefore this chapter will sought to identify the various types of social networking applications in academic libraries in Nigeria and how librarians use these social media for effective service delivery to their users, the opportunities accrued in using these applications, the various constraints in using these social networking applications in academic libraries, recommendations and the future trends will be succinctly discussed in this chapter.

BACKGROUND

Social media which are also known as social networks are tools (through the registration of profiles with their platforms) that help promote the sharing of information on real time basis, and these tools are dependent on modern digital communication like the Internet and the www (Ekuoye, 2015). In addition, social media are seen as computer-mediated tools that allow people to create, share or exchange information, career interests, ideas, and pictures/videos in virtual communities and networks (Buettner, 2015). However, social media was broadly defined to refer to ‘the many relatively inexpensive and widely accessible electronic tools that enable anyone to publish and access information, collaborate on a common effort, or build relationships’ (Murthy, 2013).

In the past, most of these relationships existed mainly among family members, colleagues, friends, church members, and others who relied mainly on face-to-face communication. Today the story is no longer the same as most of these relationships can be carried out in virtual space using social networking sites which makes it possible for people to interact on the Internet. Online

social networks can therefore, be described as relationships between groups of people carried out in virtual space.

The history of online social networks dates back to 1997 with the appearance of SixDegrees.com and there are over 100 websites which provide social networking functionalities (Boyd and Ellison, 2007). Social networking sites are two-way transparent communication that encourages a feedback mechanism; connecting people with shared interest. In the social network site, the user is a participant, a co-creator, and a builder of knowledge. The dynamic nature of this technology enables users to have an open access to knowledge and contribute local content on the social network space. This has being made possible by the tremendous growth and increase in the use of social media across the world. However, the developing countries are still lagging behind compared to their counterparts in the developed countries. This is confirmed in figure 1, which is social media use around the world.

According to Adeleye (2015), “Social media and its elements in Nigeria isn’t really as new as some people believe it is, social media started in Nigeria as a concept many years ago, but has evolved into sophisticated technology. The concept of social media invariably can be dated back to the use of the analog telephone for social interaction in the 1990s.

The emergence of social media in Nigeria has become very prevalent in every sector of the country for example in education, agriculture, aviation, health, finance, politics, entertainment and to mention but a few. Digital in Nigeria, a snapshot of the country key digital statistical indicators from Wikipedia internet live stats (2015) shows that; the total population of Nigeria is 183.5million (Urbanisation 50%) with active internet users of 70.3million (38%), active social media accounts of 13.6million (7%), mobile connections of 138.0million (75%) and active mobile social accounts of 12.4million (7%).

MAIN FOCUS OF THE ARTICLE

Issues, Controversies, Problems

Online Social Networks and Academic Libraries

The use of online social network applications is still gaining popularity in academic libraries especially in Nigeria. Although there are hundreds of websites which provide online social network functionalities, but not all of these sites are likely to offer the same degree of usefulness to academic libraries.

Many researchers from the field of library and information science are beginning to show interest in online social networks. Cook and Wiebrands (2010) researched into librarians' use of online social networks for current awareness. The study revealed that curiosity was the major reason why librarians use social networking sites.

Differing viewpoint by Charnigo & Barnett-Ellis (2007), in a survey of 126 academic librarians about their knowledge of and attitude toward Facebook, revealed that 54% of the librarians

surveyed were overwhelmingly aware of Facebook but were not involved because they did not believe that there was an academic purpose for Facebook.

However, coming down to Africa, in Kenya, Gichora and Kwanya (2015) in their study revealed that Web 2.0 tools were widely used in most academic libraries in Kenya. In fact, all the sampled libraries used one or more Web 2.0 tools. It is also evident from the findings that the use of Web 2.0 tools in academic libraries in Kenya has had a positive impact on the effectiveness and efficiency of services they provide.

Also in a study carried out on the Use of Facebook in Information Service Delivery in Academic Libraries in Niger Delta, Nigeria by Achugbue and Ogbomo (2015), they observed that the entire 15 academic libraries which represents 100% of the population of the study has no Facebook application in their libraries.

Allison (2012) noted that Social media forms part of the rich environment of scholarship within which researchers work in the 21st century, and a librarian who does not take the time to grasp these changing conceptions is doing herself and her patrons a disservice.

Social Media Apps Used in Libraries in Nigeria

Social media applications allow librarians to adopt a new role by placing themselves into a social realm with users. By reading blogs, group postings, and message boards, the librarian becomes an active participant, who is able to anticipate and advise patrons as needs arise. Linking to patron profiles also keeps the library within the consciousness of users, potentially increasing interaction (Courtney, 2007).

With the enormous popularity of Web 2.0's social networking platforms, libraries of all types have embraced them as a method of promoting themselves within their communities. Some of these Social media applications gaining popularity and popularly used by librarians in academic libraries in Nigeria for effective information service delivery to their users include:

Facebook

Carlson (2010) opined that facebook was originally developed by Zuckerberg, Moskovitz, Hughes & Saverin in 2004 at Harvard University in order to provide the students with a place in which they could keep in contact with their classmates and share study-related information. One of the primary uses of Facebook by academic libraries is to market the library with a library fan page for understanding the library users' information needs.

Facebook statistics which was updated October 2015 shows also that at 1.49 billion, Facebook has more monthly active users than WhatsApp (500 million), Twitter (284 million) and Instagram (200 million)—combined (facebook, 2015). This shows that Facebook continues to reign in popularity over other social media channels.

It is most popular now also in academic libraries in Nigeria because it is librarian- friendly, with many applications like JSTOR search, World Cat, and much more. Academic Libraries in Nigeria use Facebook, mainly to advertise the library services push out announcements to library users, post

photos/videos, share ideas, provide chat reference, and have a presence in the social network without actually visiting the library.

MySpace

MySpace, which is popularly known as a “place for friends”, is defined as “an online community that lets you meet your friends.” MySpace interface provides a number of networking tools in a simple and relatively self-explanatory interface, including facilities that enable users to send messages back and forth to each other, blog, post bulletins to friends, leave comments for other MySpace users, and instant messages.

In academic libraries in Nigeria, library users have also taken advantage of this site to post, customize catalog search tools, and blog features to improve their presence. Many libraries have seized upon the networking opportunities MySpace affords, in building their own profiles and connecting with users. However, MySpace is not as popular as facebook in academic libraries in Nigeria.

Ning (www.ning.com)

According to Educause Learning Initiative (2008), Ning is an online service that allows users to create their own social networks to join, and participate in other networks through Interaction by engaging your community directly (messaging, wall posts, blogs, and so on). Although Ning does not provide usage statistics or numbers of registered users, the company does highlight the number of networks on its platform.

Ning provides an opportunity for students to create their own social networks and learn how to cultivate and sustain a community of users that might resemble professional contacts and relationships. Librarians can get connected with users, other libraries, library associations, and more for professional growth opportunities. The Nigerian Library Association (NLA) utilizes this platform to discuss topical issues among the members.

Blogs

Blogging is an easy process for publishing ideas on the web to get the reactions of other users of the web. Libraries all over the world are using blogs for the easy dissemination of information to the targeted users. Blogs can be used to communicate library events, publicize information resources, train staff, and offer subject-related reference services (Han and Liu, 2010).

The academic libraries in Nigeria by librarians have enormous use of blogs which includes: discussion groups, writing of articles, news on topical/current issues, book reviews, research purposes, and links to library catalogue.

Wikis

Wikis are free online encyclopedia that gives a background knowledge and definition of concepts. It offers a platform for users to access, edit and contribute to content. This is a collaborative web page for developing web content. A wiki is a collaborative web site which can be directly edited by anyone with access to it.

Studies have shown that librarians use wikis to collaborate with librarians in other libraries, and that few libraries use wikis to collaborate with patrons (Kim and Abbas, 2010). In academic libraries in Nigeria, wikis are used by librarians for knowledge/ information sharing, collaboration purposes with other librarians and research purposes (multidisciplinary subject coverage).

LinkedIn

LinkedIn (www.linkedin.com) is a social networking site for professionals and career connections that can help you promote your small business. LinkedIn dominates the professional social network segment. It is one of the oldest having started in 2002. Librarians can get patrons connected with specialists in their particular field of interest via LinkedIn. Librarians can use this platform to render specialized services such as Selective Dissemination of Information (SDI).

LinkedIn, in the opinion of Marshall (2009), stands out as a worthwhile social networking destination for library professionals. Through introductions made by online colleagues, librarians can continually expand their professional contacts using LinkedIn. LinkedIn is gradually gaining popularity in academic libraries in Nigeria, because librarians and users are now building a good professional network with LinkedIn. They can also share professional interests by forming a group.

Twitter

Another social networking site gaining popularity is Twitter, a micro blogging application, to keep staff and patrons updated on daily activities. According to Olaniran (2014), twitter is an online social networking and micro blogging service that enables users to send and read “tweets”, which are text messages limited to 140 characters. Registered users can read and post tweets but unregistered users can only read them. It was created by Jack Dorsey, Evan Williams, and Biz Stone in 2006. Users access Twitter through the website interface, SMS, or mobile device apps. It is now one of the ten most visited websites, and has been described as “the SMS of the Internet”.

In a study, Perceptions and acceptance of librarians towards using Facebook and Twitter to promote library services in Oyo State, Nigeria by Omobolanle (2015); the paper revealed that majority of the libraries in Oyo state, Nigeria, have Facebook profiles, though minority have Twitter accounts with high perception and acceptance of using Facebook and Twitter to promote library services. Also a research by Olaniran (2014) showed that the students of the University of Jos use Twitter for informational, academic and social purposes. Librarians in Nigeria use this platform to give users first hand information. Marshall (2009) identified Twitter as a tool for staying current. Twitter allows users to send instant messages to social network via short messages, also known as micro-blogs.

Discussion Group/ Online Forum

The first library online professional group was the Nigeria Library Association (NLA) forum (nla-online-forum). Librarians from all institutions in Nigeria enroll in this group by subscribing to it. This allows the librarians to exchange information on professional opportunities, professional events and new technologies within the Library and Information science field. This national group has continued to grow in leaps and bounds.

YouTube

YouTube provides the user with the ability to save favourite videos, create a playlist, rate videos, make comments about them, and share them with other users (Buckley, 2008). In academic libraries in Nigeria, events such as important highlights of inaugural lectures, talks, conferences, seminars and workshops are disseminated via the YouTube.

Flickr

Flickr is known largely as a photo sharing web site, it also allows users to post video. Academic Librarians in Nigeria are using this tool to share library photos, create discussion groups, distribute new images of library collections, and a virtual tour of the library. Cover page of new arrivals of both books and journals can be disseminated to users via Flickr. It can also be used to enlighten users on topical issues such as the different pictures of emblems of the political parties in Nigeria; on-going elections in Nigeria, many Public and Academic libraries put this to great use.

Library Thing

Library Thing is a social networking tool that enables users to catalog their books. This is done through the library OPAC, once an account is created, a list of books with ISBNs is sent to Library Thing which sends back a piece of code which is pasted into the footer of the Library OPAC. Aca-

ademic libraries in Nigeria are utilizing this to send a list of current publications to their library users.

Really Simply Syndication (RSS)

Xu (2007) found that blogs, IM and RSS were the main Web 2.0 applications which have been used extensively by academic libraries of New York State and Long Island in the USA. Libraries have already been making use of this new internet tool for disseminating library news and current alerts. Some of the Nigerian academic libraries major purpose of providing RSS news feeds in their library web sites includes: to disseminate library events, new arrivals, exhibitions, catalogue search, publishing library news and bulletins.

Instant Messaging (IM)

Instant Messaging (IM) is also a very useful tool which helps library professionals to provide library services. Some academic libraries in Nigeria currently use IM mainly to provide online reference services. "Ask a librarian" services are provided by instant messengers all over the world. Reference questions are answered immediately without the need to go to a reference desk. Librarians and patrons both appreciate the fact that instant messaging is faster than traditional chat services, and librarians also like the fact that the software can be downloaded for free (Houghton and Schmidt, 2005).

Opportunities for Libraries

The different sectors in the country have adopted the use of social media due to certain features which makes it more unique and accessible than the traditional media. Such features include and are not limited to affordability, availability, timeliness, current / easy updates, immediate feedback and flexibility.

In a study carried out by Onuoha (2013), it established that librarians in Nigeria actively seek means of developing themselves professionally.

Although various forms of social media applications exist, the valid empirical evidence showed that librarians in Nigeria use mostly online discussion forums, online social networks such as Facebook, Wikis and blogs for professional development, while social bookmarking tools, virtual world, podcasts and photo sharing sites are used minimally. Social networking presents some important opportunities to libraries which include marketing of library services and reference services (Ezeani & Igwesi, 2012).

However, some opportunities accrued to the libraries through social media are:

1. **User-Friendly:** The social media apps are user friendly because the users can fully participate, collaborate and interact with the librarians without restrictions and are allowed to make contributions as well.
2. **Reference Services:** Quick dissemination of information is attained by responding to the library user's complaints, queries, comments and feedbacks without physically visiting the library.
3. **Advertising / Marketing of Library Services:** Libraries can now publicize their library events, advertise new library resources / new arrivals, library orientation, exhibitions/ displays, book fair, library bulletins /news, seminars, talks and so on, are all made available on these platforms to promote the library services to their library patrons.
4. **Affordable Price:** With the emergence of social media, delivering information to the library users is now affordable notwithstanding the economic situation of the country which has affected the library too. According to Njoroge and Kang'ette (2013) social media is now a means of cheaper communication that is instant and fast.
5. **Enhances Information / Knowledge Sharing:** Librarians now provide and share more current and up-to-date information to their library users.
6. **Socialization:** Social media has increased the discussions, interactions and connections between librarians and their library users, librarians and other librarians/other staff of the school community including other professionals in different sectors, in order to keep abreast with new developments.

Problems Associated with Use of Online Social Media

Nigeria has several factors that militate against the use of Information Communication Technology (ICT) generally. According to Gbaje, (2007) the erratic nature of electricity supply in the country will not support the successful implementation of the new information trends like social networking in libraries in this age of modernization. Some of the major challenges faced by the intrusion of social media in academic libraries in Nigeria are as follows:

1. **Unsteady Power Supply:** This is assumed to be the greatest challenge faced by every sector in the nation and the academic libraries are not exempted. This has made most libraries to fail in the effective service delivery to their library users, as most libraries cannot afford the cost of running a generator daily.
2. **Poor Funding:** Without proper funding of the libraries and adequate budget allocation to libraries, they will not also be able to incorporate the social media into their various libraries.
3. **Inadequate Training:** Most librarians are not trained in these new modern technologies and are most times not sponsored by their institution to attend training sessions to update themselves. According to Kemrajh (2013), librarians are not given adequate time to embrace the technologies and social media is not given a priority in library work.
4. **Resistance to Change:** Most librarians still prefer to carry out their library operations using the traditional method than using the

modern methods. Some of their reasons are due to traditional beliefs (technologies are for the white man), negative attitudes, lack of computer self efficacy, technophobia and so on.

5. **Lack of Privacy Policy:** Most of the libraries have not developed or implemented Social Media privacy policies in their libraries hence copyrights, privacy, and other legal rules are not complied with. This can pose a security risk to the users if perpetrators take advantage of their personal information displayed on the social networking websites.
6. **Academic Fraud:** According to Adeleye (2015), academic fraud is also part of the negative side of social media since its inception in Nigeria, as many people copy another person's work online without acknowledging the real owner of the work, otherwise called plagiarism.
7. **Addictive Behaviours:** Many studies have shown that the extensive use of social media can actually cause addiction to users. Most users especially the undergraduates are victims of this behaviour.
8. **Social Violence:** There has been a rise in social violence activities in Nigeria. Some of the social violence witnessed in Nigeria from 2008 to 2015 has resulted in the death of the victims. Others were kidnapped, raped and molested through people they met on social networks.

All these and many more limit the full incorporation of social media apps in academic libraries in Nigeria for effective service delivery to their library users.

SOLUTIONS AND RECOMMENDATIONS

With respect to the foregoing the following recommendations were put forward:

1. Provision of stable power supply will encourage and facilitate the effective use of social media applications.
2. There is need for social media to be given priority by training librarians to in social media / networking applications.
3. The budgetary allocation to libraries should be upgraded to enable libraries afford the necessary facilities for social media applications.

FUTURE RESEARCH DIRECTIONS

The emergence of social media applications due to modern technologies in the society has brought about its intrusion in academic libraries all over the world and also in Nigeria. Future research directions should be towards the privacy policy issues in using the social media/ networking applications in academic libraries in Nigeria to reduce the social violence rate. The educational purposes of social media in embedded librarianship, teaching and learning should be looked into as well. Also entrepreneurship in using social media in academic libraries is required to be addressed.

CONCLUSION

This chapter examined issues pertinent to the intrusion of online social media in academic libraries in Nigeria. Indeed, the benefits of using social media applications in libraries cannot be overemphasized; it is obvious from existing literatures that there is no clear indication of a positive use of social media applications in performing library services by librarians in Nigeria. However, where there is the intention to use these media factors such as; unsteady power supply, poor funding, lack of training and so on appears to constitute aberrations. As such, there is a need for pro-active measures to encourage the use of social media applications in academic libraries in Nigeria.

KEY TERMS AND DEFINITIONS

Academic Libraries: These are libraries established in higher institutions like universities, polytechnics and colleges of education.

Information Delivery: This is the act of conveying information from one person to the other or from one place to the other.

Library Services: These are the various services rendered in the library to their users.

Nigeria: This is the most populous country in Africa otherwise known as giant of Africa.

Social Media: Online networking tool for interaction, communication and sharing of information among group of people.

Social Networking: This is the platform for people to connect, interact and discuss with one other.

Socialization: The act of interaction, information or knowledge sharing among group of people.

Web 2.0 From Evolution to Revolutionary Impact in Library and Information Centers

INTRODUCTION

Technological revolution is affecting different facets of social life, although there is some disagreement in the research regarding the positive and negative influences. The Internet allows greater flexibility in working hours and location, especially with the spread of unmetered high-speed connections. The World Wide Web is most significant technology after the advent of printing press. It is a global set of large number of resources interrelated by hyperlinks. Social Networks, RSS Feeds, Wikis are a part of Web 2.0 which is most advanced form of the web. It can be well articulated as the shift from simply being a website and a search engine to a shared networking space that drives work, research, education, entertainment and social activities, which essentially all people do. Web 2.0 applications are socially rich and community building is the core of these applications. A key element of the technology is that it lets people to create, share, collaborate & communicate. The Web 2.0 differs from ordinary websites as it does not require any web design or publishing skills to participate, making it easy for people to create and publish or communicate their work to the world. The nature of this technology makes it an easy and popular way to communicate information to either a select group of people or to a much wider audience.

The Web 2.0 paradigm has gained substantial momentum in the last decade. The influence of Web 2.0 principles and technologies has fuelled an explosion of information and media content on the Web, and individual and corporate adoption of the technologies continues to rise. In this milieu it is imperative to understand and learn about the present and evolving web 2.0 tools and their application in different walks of life. The proposed study made an endeavour to dig deep into the genesis, development and application of various Web 2.0 tools in library and information science.

The Internet allows greater flexibility in work, especially with the spread of high-speed connections. Internet-based technologies nowadays are playing a significant role in the way that societies communicate with the each other. It's a fact that the technologies allow information to be readily exchanged without geographic and time barriers. Many people use the terms Internet and World Wide Web synonymously. The World Wide Web is a global set of large number of resources interrelated by hyperlinks. It provides a mesh of services including email, social networking and Web 2.0. The Web 2.0 is not mere a website and a search engine but it furnishes a platform for research, education, entertainment and social activities, which essentially all people do. It also provides the services like blogs, wikis, and multimedia sharing services, content syndication, podcast-

ing and content tagging services. Applications of Web technology have been in use for years now, although new features and capabilities are being added on a regular basis. It is remarkable to see that many of these recent technologies are concatenations, i.e. they make use of existing services. World Wide Web (WWW) provided the base for Web 2.0 applications to create a new communication environment (Linh, 2008). It is a second wave that covers web tools and services. Davis (2005) describes Web 2.0 as an attitude not a technology and Birdsall (2007) believes that Web 2.0 is a social movement. So the Web 2.0 applications differ from Web 1.0 applications by their frequency of usage too. As the Web 2.0 applications are socially rich and community building is the core of these applications, so their usage increases many times than Web 1.0 static websites/applications. In 2004, Tim O'Reilly, the founder of O'Reilly Media (www.oreilly.com), used the term web 2.0 to describe the significant shift in how software developers and users were using the web. One of the characteristics of Web 2.0 web sites is that people go there to do something – as contrasted with Web 1.0 “brochure ware” sites that people came to primarily for information. Unlike in the past when it took months or years to implement new software, today we can download, set up and use powerful applications without the intervention of a technology expert. We can create our own website, manage huge databases, and stream rich media, the credit for all of this goes to the evolution of web. The users get attracted by these kind of experiences while they are added to the library environment. As per Dye (2007) libraries often impressed and get encouraged to use Web 2.0 technologies. These libraries that have adopted, implemented and embraced Web 2.0 technology are referred to have “Library 2.0” competences. As per Maness (2006) Library 2.0 offers various services like virtual reference services, databases, catalogue tagging, and downloadable media for home users. As Houghton-John (2005) defines it, Library 2.0 “simply means making a library’s space (virtual and physical) more interactive,

collaborative, and driven by community needs.” Library 2.0 has numerous façades reflecting the distinctive paths of user involvement that Web 2.0 facilitates. These façades comprise social networks; wikis; social bookmarks; blogs; photographs and audio; podcasting; videos; presentations; images; bibliographic reference managers; content syndication; messaging; video conferencing; chat, and much more.

BACKGROUND

Web 2.0 enable us to identify the various types of connections online environment avails to the users. Three key aspects of Web 2.0 have been identified in this regard, which are *Interpersonal Computing*, *Web Services*, and *Software as a Service*. Interpersonal Computing is about using the online technology to connect people to each other in social networks or business teams. The key Interpersonal Computing aspects of Web 2.0 are as SNS, Blogs, Wikis and online videos. All of these sites allow anybody to access as well as to add content. It allows users to leave messages and comments and also to exchange digital media in form of photos and videos etc. *Web Services* are components of online functionality that can be plugged together like the kind of digital letter in order to create integrated online offering or mashup. The final key aspect of Web 2.0 is ‘*Software as a Service*’ (*SaaS*). This involves application functionality being offered directly over the internet. In turn used data and application can then be accessed through internet enabled computing device (Barnatt, 2012). In addition to this, Web 2.0 can be described in three parts. (i) Rich Internet application (RIA) — defines the experience brought from desktop to browser whether it is from a graphical point of view or usability point of view. Some buzzwords related to RIA are Ajax and Flash. (ii) Web-oriented architecture (WOA) — is a key piece in Web 2.0, which defines how Web 2.0 applications expose their functionality so that other applications can

leverage and integrate the functionality providing a set of much richer applications. Examples are feeds, RSS, Web Services, mash-ups. (iii) Social Web — defines how Web 2.0 tends to interact much more with the end user and make the end-user an integral part (Web 2.0, 2013). Further, there are a number of Web-based services and applications that demonstrate the foundations of the Web 2.0 concept, and they are already being used to a certain extent in libraries. These are not really technologies as such, but services (or user processes) built using the building blocks of the technologies and open standards that underpin the Internet and the Web. The introduction of Web 2.0 tools into library mesh sites inspires collaboration or communiqué between customers and the library that drives afar than physical services increasing the prospective of library facilities to patrons situated afar from the corporeal organization. Libraries have evolved in terms of the standards and technology used specifically. For example The Young Adult Library Services Association's (YALSA) Public Library states that *"Young Adults Deserve the Best supports the use of social networking and Web 2.0 services like blogs and podcasts in the classroom and library"* (Husid, 2010). Linh's (2008) study examined the actual use of Web 2.0 at Australasian university indicates that the web 2.0 applications are well used in the university and further revealed that most popular applications were blogs, wikis, RSS, messaging, social networking, and social tagging. A similar study by Han and Liu (2010); Si, Shi, and Chen (2011) while conducting the similar study of Chinese university libraries, had yielded nearly identical findings.

WEB 2.0 SERVICE AND THEIR APPLICATION IN LIBRARIES

The prominent Web 2.0 services and applications are wikis, multimedia sharing services, content syndication, podcasting and content tagging services etc.

Blog

The term blog originally come from the phrase "web-log", which refers to a simple webpage containing paragraphs of opinion, information, personal diary entries, or links arranged in a chronological order with the most recent entry first in the style of an online journal (Doctorow, 2002). Blogs, which represent the earliest form of Social Media, are special types of websites that usually display date-stamped entries in reverse chronological order. Blogs have a variety of formats and might include the user expressing their opinion about a topic or documenting activities. Blogs are interactive in the sense that other users could provide comments on the information posted by the blog author. The educational applications of blogs include researching, tracking, interpreting, and evaluating blogs for political commentary (multiple perspectives), cultural events, business, or other news and for examining changes over time (Alexander, 2006). A blog takes in a user-friendly commentary format with separate postings rather than a threaded discussion board (Richardson, 2006). Blogs are personal Web diaries, where users can offer their ideas, experiences and opinions on any topic. Technorati (Internet search engine for searching blogs) currently counts around 112 million blogs worldwide with many more being added every day (Wright, 2013). Blog entries may include video and other rich media depending on the blogging software or service that is used. Blogs are now also employed by libraries for giving due publicity to their new activities, events and services and as such acts as a platform to get instant user feedback from cross section of the population. Rogers (2015) in his study found that 96% of the selected library websites featured an RSS application. In fact, the most common RSS application was employed for new book arrivals, book appraises, whereby libraries displayed book jackets or abstracts of the afresh titles. This way libraries can plug the holes and achieve excellence in their endeavours..

Wikis

The word Wiki originates from a Hawaiian term which means “quick” or “Super-fast”. As popularly known a wiki refers to a web site that anybody can edit. Knowledge in the Web 2.0 environment is built directly by the users. Some of the most popular tools for building shared knowledge are so-called wikis. Wikipedia’s popular success has meant that the concept of the wiki, as a collaborative tool that facilitates the production of a group work, is widely understood. (Ebersbach, & Glaser, 2006). The first wiki was launched by Howard G Cunningham whose wiki site was named as WikiWikiWeb on March 25, 1996. Wagner and Bolloju (2004) are of the view that as wikis are informal technology, they are effectively used for temporary problems with dispersed knowledge foundations. In the context of libraries, Wikis can aid reference librarians fill knowledge management requirement. It can be used as a ready reference database for FAQs. It can also be used as knowledge repository (Cohen, 2005). Wikis can also be used as cooperative booths to help accomplish knowledge for specific projects or teams in library reference services (Frumkin, 2005). “WikiRef” created by Reference Librarians of Butler University and “Biz Wiki” at Ohio University Libraries envisioned to be a joint review of reference resources (Kille, 2005).

RSS

RSS stands for Really Simple Syndication or Rich Site Summary. It is a technology which has brought about a significant advance in the fundamental architecture of the web (O’Reilly, 2005). It allows you to keep up-to-date with news and information from your favorite Web sites. RSS is a family of Web-feed formats that support the syndication of Web content. (This means making information and data on a Web site available to other Web sites.) The feeds notify people when new material is added. The feeds can provide text-only summaries, full pages of content, audio

(podcasting), or video. The feed receiver benefits from access to fresh and timely material that can be used on his or her own Web site to make it more interesting to visitors. The feed sender benefits from the increased exposure and traffic the feeds draw (Stiefvater, n.d.). RSS feeds is age old alerting service offered by libraries in new form and format. Libraries in digital environment can offer CAS and SDI services to the users using RSS feeds. Varnum(2006) provides a detail about how libraries use RSS feeds for patron use. *BlogBridge: Library (BBL)* is an application based on RSS which when mounted in a library’s system and attached with the social network of the library, will permit customers to take a solo, personalized, personal library page that groups all the library material to their research (Maness, 2006). RSS feed if facilitated to scientists and professionals can help them to do better in their respective areas.

Podcasts

A combination of the words “iPod” and “broadcast,” podcasts are digital media files distributed over the Internet and listened to on a portable media player. A related term is “vodcast,” which describes podcasts that incorporate video. Podcasts were originally conceived as a way for people to create their own radio shows without needing a recording studio or transmission network. They evolved into a means of recording and distributing speeches, classes and training sessions, and public safety messages. Podcasters and vodcasters record their audio and video sessions, edit them, and upload them to a feed. Listeners and viewers use a “pod catcher” service such as iTunes to search for and subscribe to one or more feeds. When a new podcast or vodcast is released on the feed, the audio or video file will download automatically to the subscribers’ iPod, computer, or other device so that they can listen to or view it at their leisure (Stiefvater, N.D). Publishing audio and video recordings of lecture materials and class discussion on a podcast is a popular way of in-

formation sharing among the new generation of students, teachers and social workers. Originally podcasts were called audio blogs and were the beginning efforts of adding audio streams to early blogs (Felix & Stolarz, 2006). Libraries being the centres to give neutral and non-judgemental platform to users can offer users virtual space to host their podcasts/vodcasts. Since most of the podcast/vodcast publishers and users are youth therefore, this move if taken has the tendency to make library once again nerve centre of knowledge sharing organisations.

Tagging and Social Bookmarking

A tag is a keyword that is added to a digital object (e.g. a website, picture or video clip) to describe it, but not as part of a formal classification system. Application of tagging was initiated in Joshua Schacter's del.icio.us website, who launched the 'social bookmarking' phenomenon. Social bookmarking systems have many features in common. They facilitate users to generate lists of 'bookmarks' or 'favorites', to store these centrally on a distant service and to share them with other clients. The idea of tagging has been expanded to include what are called *tag clouds*: groups of tags (*tag sets*) from a number of different users of a tagging service, which collects information about the frequency with which particular tags are used. This frequency information is often exhibited graphically as a cloud in which tags with higher frequency of use are displayed in larger text. Social bookmarking services such as Diigo or del.icio.us enable users to store lists of Internet resources they find useful and make them accessible to others with similar interests (Ktitraci, 2009). 'Social bookmarking' is the trend which was first motivated by the popularity of tagging sites such as del.icio.us (Anderson, 2007). Literature shows that the use of Social Bookmarking sites is not up to mark in the library environment. Maness (2006) suggests that tagging, or social bookmarking unambiguously, are "excellent resource discovery tools" which aid libraries to locate and share the

resources to its patrons. Therefore libraries have to play a proactive role to educate and equip users about the impact and benefits of these wonderful tools so that they can make most of this service.

Instant Messaging (IM)

Instant messaging (IM) is a collection of technologies that create the possibility of real-time text-based communication between two or more participants over the internet or some form of internal network/intranet. IM is an integral tool for reference services in terms of chat services. It could improve the timeliness of user interaction and the user's initiative, help libraries investigate user's requirement clearly and concisely in time, which is helpful to answer the questions (Si, Shi & Chen, 2011). Instant Messaging or "chatting" is a popular method of exchanging text messages in real time. Popular IM applications include WhatsApp, Facebook Messenger, AOL's Instant Messenger (AIM), Microsoft's Messenger, Google Talk (Hangouts) etc. IM (including text messaging) is fast replacing e-mail, especially among students. Libraries in present times can exploit IM technology as the real-time reference service to its users. Since the present generation is more tech-savvy particularly choosing Instant Messaging as the mode of communication, libraries can play an imperative protagonist to deliver information to its community via this web 2.0 tool. Maness (2006) states that the instant messaging reference services can be encouraged when certain consumer information seeking behaviors are perceived. It helps Librarian to know when users are vanished, and will offer instantaneous, prompt and real-time assistance.

Social Networking Sites

Another application of web 2.0 that has facilitated the timely and fast interaction among people in a more convenient way is Social networking sites. These sites displays user profiles, social links, and a variety of added services and enables users to share

views, thoughts, activities, events, and interests within their individual networks over the internet through e-mailing and instant messaging (Hossain & Aydin, 2011). Social networking sites act as a channel via which the user can share personal multimedia like audio and video clips, images, geographical location, contacts etc. It further allows users to restrict viewing of their personal information by means of privacy settings. (Wikis, Blogs & Web 2.0 Technology, 2008). Networking Sites like Facebook, Twitter, MySpace and LinkedIn facilitates online communication in between friends, colleagues and even strangers (Ktitraci, 2009b). Social networking sites allow users some control over the look and feel of their pages and can be customized with add-ins and “gadgets,” small software applications that provide information or amusement. Social network is the most prominent tool used to connect with the user community and libraries are no exception to it. In the present digital age, libraries can provide services and content to its users by providing information using social networking sites like Facebook. These networks can also be used to promote the libraries on wide platform. It provides a podium to libraries whereby information can be shared anytime and anywhere. *LibraryThing*, a library-based social network facilitates users to catalog their books, how librarians endorse reading to users. *LibraryThing* allows users, to recommend books to one another by seeing other’s collections. It also allows them to connect asynchronously, blog, and “tag” their books (Maness, 2006). SNS were found to be the third common used Web 2.0 feature with 55 libraries having one or more account

File-Sharing Sites

File-sharing sites let users upload files, photos, and videos for others to view and download. Users can also create an individual profile and list their favourite photos or videos (Wikis, Blogs & Web 2.0 Technology, 2008). They usually include feedback tools that allow others to rate and comment. The most popular are Flickr and Photo bucket for shar-

ing images and YouTube for sharing videos. YouTube is the most widespread video sharing site in the world. It enables users to share and watch their own, or downloaded, videos, rate or comment on them. Flickr is a platform for uploading, sharing and storing pictures. PodcastAlley is also other file-sharing site where users can search for and listen to podcasts uploaded on the internet (Wright, N.D b). Since file-sharing sites are considered to be the present day digital libraries, they can be particularly used for e-book requests which helps in collection development of libraries.

Mash-Ups

A mashup is a term used to refer to a website or webpage that combines data and services from various sources on the Web (Murugesan, 2007). A mashup, in web development, is a web page, or web application, that uses and combines data, presentation or functionality from two or more sources to create new services. Mashups can be divided into seven categories: mapping, search, mobile, messaging, sports, shopping, and movies. More than 40% of mashups are mapping mashups (van der Vlist, 2006). A mash-up is a Web application that combines data from more than one source into a single integrated tool. An example is the use of cartographic data from Google Maps to add location information to real estate data. This creates a new and distinct Web service that was not originally provided by either source (Wright, n.d.). There are many types of mashup, such as business mashups, consumer mashups, and data mashups. Map mashup is the most popular among them. Libraries in present times have lots of opportunities to use mashups to deliver and help deliver through their websites, offering new and interesting services to the users. Library 2.0 is itself a mashup. It is a hybrid of wikis, instant messaging, content aggregators streaming media, blogs and social networks. It lets the user to edit OPAC data and metadata, IM chats with librarians, protects the user’s tags, wiki entries with additional users and the user is capable to control access to their

profile; borrow and lend tags, and a massive user-driven catalog is generated and mashed with the traditional catalog (Maness, 2006). For example Cambridge Libraries have used map mashup on their website to locate their library.

FUTURE RESEARCH DIRECTIONS

Web is fast-evolving from simple Web to Web 2.0 to Web 3.0. This evolution is fascinating users and the expectations are increasing. The momentum must be maintained by the Web developers so that in coming years with the addition of virtual reality and semantics, the web would be whole new thing for professionals. In this milieu it would be in the fitness of things to understand user requirements and perceptions and how library professionals can mould it to their advantage. The manipulation and timely application of evolving web would keep us in focus and as such a profession sought after. Therefore the possible future areas would be Web 2.0 services and usability, Web 3.0, role and implications for libraries, application and utility of virtual reality in library and information centres. Further research could be directed on the use of Web 2.0 on academic libraries, which would offer a wider depiction of Web 2.0's acceptance at a whole.

CONCLUSION

Web 2.0 provides users with a plethora of opportunities for social interaction and collaboration. In a very large extent, Web 2.0 has greatly modified the way people using the Internet. People use web 2.0 applications to pool their knowledge. Web 2.0 not only emphasizes effectiveness and usefulness of its applications, but a major focus is on the social utility and entertainment. Web 2.0 provides an interface to users in terms of social interaction such as Facebook, entertainment such as YouTube and communication tools such as Blog. That is why Web 2.0 becomes more and more popular

in the Internet. Libraries form an essential part of academic institutions. Their role transcends the mere function of depositories of published information sources. Academic libraries have traditionally enabled and facilitated the exchange and growth of information, knowledge and culture among teachers, students and the general public. In this sense libraries represent a focal point of academic life and as such serve also a societal purpose of bringing together people around common themes. This purpose is nowadays enhanced and facilitated by the use of technology and, in recent times, by the so-called Web 2.0 (Maness, 2006). Although libraries select to "wait and see", and thus accept Web 2.0 somewhat sluggishly or even unenthusiastically, it is vibrant that "Library 2.0" is not a transitory trend. Libraries are indicting these applications and features to do their job, but in innovative ways: meeting patrons' needs. Thus, this service-based, and is attractive and instrumental to libraries with users that live are at excessive topographical distance from the library itself. A contemporary academic librarians are re-imagining library collection development. Instead of purchasing books, librarians are leveraging Web 2.0 applications for knowledge production and management by facilitating collaborative open access e-publication alternatives to textbooks for student and research use.

Logistics and Supply Chain Management

Barcodes vs. RFID and Its Continued Success in Manufacturing and Services

Amber A. Smith-Ditizio
Texas Woman's University, USA

Alan D. Smith
Robert Morris University, USA

INTRODUCTION

Versatile Nature of the Ubiquitous Barcode

A barcode is a machine-readable code in the form of numbers and a pattern of parallel lines of varying widths, printed on a product (Sirico, 2010). Barcodes are essentially a type of symbolic language that uses printed horizontal strips of vertical bars used for identifying specifications. An accompanying scanning device reads the barcode by moving a beam across the symbol (McCathie, 2004). Barcodes can come in one-dimension (1D), 2-dimension (2D), or three-dimension (3D). Barcode systems are used in routine business from the manufacturing and ordering process to the parking lot after purchased. Joseph Woodland and Bernard Silver invented the barcode in 1949. Silver overheard a conversation of a supermarket executive from a food chain called Food Fair. The general rationale was to have an automatic system for capturing product information (Seideman, 2015).

Barcode technologies have had a relatively long history with almost every type of business that keeps track of goods and services. Point-of-sale (POS) is probably the most common use for the barcode (Chen & Dubinsky, 2003). Customers typically view barcodes on almost every item that is available for purchase within a retail environment. The cashier uses the barcode to scan the items into the computer system and retrieve the amount the customer will owe for that particular

item. Barcodes in manufacturing help in inventory control, quality control, and help measure productivity throughout the manufacturing process. Barcodes are used for packaging, tracking time and attendance of employees, and measurement of proficiency (Jain, Benyoucef, & Deshmukh, 2008; Kamhawi, 2008; Kay, 2007; Kearney, 2005; Kennedy & Widener, 2008; Koong & Lin, 2007). Evaluating the efficiency of barcode systems routinely reduce costs while improving quality, on-time performance, and reducing errors.

BACKGROUND

The future need for barcodes will probably be increasing due to its universal acceptance and easy-to-use with low costs of producing barcodes (e.g., it is usually included in the cost of printing labels or packaging materials on products) (Cowles, Kiecker, & Little, 2002; Davis, 1989; Devaraj, Fan, & Kohli, 2002). As the population grows, so does the need to make workplaces and their environments more efficient and safer. Barcodes are employed in supply chain management (SCM) applications in the healthcare industry. The use of barcodes in healthcare facilities allows hospitals to save space and reduce overstock by ordering the supplies needed daily (Harrop, Das, & Holland, 2016). In the retail setting, barcodes are becoming a part of smartphones with apps. The consumer can shop and scan items through the convenience of their phone. This easily enables

the retailer to track consumers' spending. A majority of manufacturing companies are turning to the barcode system as well. The use of barcodes in manufacturing facilities assists in making the manufacturing process faster and more efficient. However, with barcodes, as with all IT-intensive technologies, have important advantages and disadvantages to consider, as illustrated in Table 1.

Barcodes are extremely easy-to-use and generally require little to no training for users. The time saved by scanning a barcode is substantial to the amount of time that would be spent manually entering product information for one or one's entire inventory. Two-dimensional (2D) barcodes reduce error and read accurately when scanned. Linear or one-dimensional barcodes are limited in their accuracy since the scanner and barcode must be properly aligned for the information to be captured. Barcodes are generally the most cost efficient method of technology for coding information, but associated equipment such as POS or inventory tracking software and scanners, etc., can quickly increase the initial costs, including replacement costs. Security on barcodes is not good, as most information coded in barcodes readily found.

Undoubtedly, there are other issues that need to be generally discussed [e.g., total quality management (TQM), lean manufacturing, just-in-time (JIT) manufacturing, waste management, change management as well as numerous other practices that are comparable to the strategy of adopting AIDC] and how the results of this can

effect whether or not the AIDC-based technologies would be successful. As evident from recent headlines, the need to maintain the privacy and ethics of personally identifiable identifiers (PII), and some companies have been accused of prying and collecting data that were always consented. In a recent study, experts believe that the use of RFID will increase from 12 million in 2011 to billions by 2021 applications Irani, Gunasekaran, & Dwivedi, 2010; Smith & Rupp, 2013; Ustundag, 2010; Visich, Li, Khumawala, & Reyes, 2009). Even if the pros outnumber the cons, it still does not answer the question if management will take the long-term and choose to take advantage of the opportunity. Such technologies have been improving at an exponential rate and many studies (Bhat, 2008; Baxter & Hirschhauser, 2004; Biswas & Sarker, 2008; Browning & Heath, 2009; Cavaleri, 2008; Chan & Kumar, 2009; Devaraj, et al., 2002; Drejer & Riis, 2000; Gaukler, Özer, & Hausman, 2008; Grewal, 2008) have suggested that result of implementing AIDC with lean technologies will have positive outcomes. This is especially associated with the expectation that costs will drop for both the manufacturers and subsequently the consumer.

Advantages of RFID over Barcodes

The general advantages of RFID-related technology only make sense where it provides advantages over barcodes (Green & Khermouch, 2005). Some of the important advantages that RFID has over barcodes include the following (Harrop, 2010; Smith, 2005a, 2008):

1. Speed, since a RFID reader can read tags faster than a typically barcode scanner can scan barcodes. For example, RFID readers designed for supply chain operations can perform up to 1,500 read operations per second;
2. Read distance, as it is common to read RFID tags at distance of at least three meters between the tag and the antenna and the read field is three-dimensional;

Table 1. Selected advantages and disadvantages of barcoding as a part of identification technologies

Advantages	Disadvantages
Inventory Control (through tracking and essentially error-free readings)	Costs (associated equipment and replacement costs)
Accuracy (2D, 3D Barcodes), Error reduction	Accuracy (especially with linear barcode)
Time savings	Limitations by line of sight scanning
Easy-to-use	Security issues, as they are easily read

3. Simultaneous as opposed to sequential scanning, since RFID readers can identify multiple tags within the read field;
4. Non-line of sight, as radio waves can penetrate most materials depending on the frequency utilized;
5. Durability, since RFID tags can operate in extremely rugged working conditions and can be encased in plastic or even embedded directly into the products manufactured.

However, barcodes can be easily printed or applied directly on the products it is designed to identify as extreme accurate read rates and very low costs.

Inventory and Operational Decisions and Cost Analysis

Inventory-related challenges include ensuring stock arrives at the right place in production at the right time, that the correct quantity is delivered as promised, and inventory shrinkage is reduced. By enabling operations managers to automatically and accurately track the flow of crucial materials through the facility, RFID tags can streamline processes and reduce costs, leading to a leaner organization (Hu, Wang, Fetch, & Bidanda, 2008; Jain, Benyoucef, & Deshmukh, 2008; Kennedy & Widener, 2008; Scherrer-Rathje, Boyle, & Deflorin, 2009; Smith & Offodile, 2007, 2008, 2009).

In order to be successful with utilizing RFID technology, a manufacturing company will need to take a risk and jump at the opportunity before the competitive advantage is no longer available. Once this happens, efficiency and effectiveness will remain the result of the implementation of the product, however, there will not be an opportunity to be ahead of competition, only to be at the equivalent level of production as them. When analyzing the efficiency affects the AIDC-related technologies would have on a production process in the manufacturing industry, there is one main goal: improving the supply chain and hopefully

reorganize the structure of the company involved. The end result will be lowered costs and eliminate any unnecessary products or processes involved in production. The value of such technologies is that it adds to a company in its ability to achieve these levels of efficiencies.

CASE STUDIES OF BARCODES IN USE

Wal-Mart Applications

A well-known retailer that relies heavily on the use of barcodes is Wal-Mart. Wal-Mart uses an integrated barcode system in conjunction with a JIT inventory system to aid in their inventory and tracking management (Burgin, personal note, 2015). Wal-Mart uses barcodes and RFID tags in 937 Stores, 2,527 supercenter, 138 neighborhood markets, 129 distribution centers, and 566 Sam's Club stores. In a typical year, Wal-Mart will spend US\$6.4 million in readers to scan barcodes and RFID's in order to keep inventory and employees updated in their computer systems at all times (Chen, 2015).

During an interview with a Wal-Mart Assistant Manager at Clarksville, TN, Burgin explained the route a barcode takes from warehouse or vendor to the consumer's home. The JIT-based inventory system starts at the checkout of a product by a consumer. Suppose a customer purchases a bottle of Tide laundry soap. When the bar code is swiped across the register, the inventory system automatically does several functions. First, it makes a list to be pulled from the back room for the midnight shift; this is called a pic list. Then, the computer generates an order list based on what items sold that day. If there were 5 Tide laundry soaps sold today then the system would tell the midnight associate to pick 5 Tide laundry soaps to restock the floor. When the bin in the back is empty, the computer automatically reorders the allotted standby amount. The JIT inventory system

reduces the amount of space needed to store extra product. It allows the store to receive 3 inventory trucks a week. This keeps the shelves fully stocked.

Once a truck arrives at Wal-Mart, the receiving manager will either accept or decline the truck. When the truck is accepted, the inventory of what is on hand in the store will automatically update as it passes through scanners at the back door. This process saves time, and eliminated two jobs when installed. The scanners are able to read each barcode as it passes through the backdoor and updates the inventory. The scanner at the back door and the high frequency tags that Wal-Mart uses are a little costlier than regular barcodes. The rewards from the use of the scanner and high frequency tags outweigh the initial costs of the new system. Once a truck is accepted and product is in the store, the store employees move all the needed stock to the floor to be processed and stored. After the inventory is stored, the customers have the opportunity to pick it up and purchase it. At the cash register, the barcode is scanned again to record the sale of each item for the consumer and the retailer. The consumer gets the barcode put in to numeric form and on a receipt. The retailer after purchase uses the barcode to allow the inventory system to update the on-hand in store amount and order more if the amount left in the store is below the shelf cap.

There is a label on every shelf in Wal-Mart. Each label has a barcode. When an associate scans the barcode it tells them how many of each product go on each shelf, how many rows, how many in each row, and how many are in the store. Employees can use a Telxon gun to see where each item in the store goes and gives the employee shelf number and quantity in the store. This function of the barcode helps keep Wal-Mart uniform and keeps the associates on track for stocking. At the end of every shelf, there is a barcode. This barcode is scanned by department managers to see how many of each shelf is either on the floor in use or in the back stock room. Having the ability to know how many shelves a store has prevents the store from overspending on hardware for the store. Wal-

Mart uses barcodes for the independent vendors. Each vendor has their own unique barcode for their use. When a vendor restocks their endcaps and shelves the vendor must put the amount of inventory added to the store manually. This allows enhanced accountability to be on the vendor side.

The barcode system is used on soft lines and grocery departments, as well in the pharmacy and deli departments. Wal-Mart has a barcode for every department in their store. The pharmacy's JIT inventory system works similar to the rest of the store. When a prescription is filled the back computer automatically places an order to replace the consumed medicine for that order. The only difference is when pharmacy trucks are accepted at the store. The computer does not automatically update when entering the store. A pharmacy manager must manually input all orders when receiving them to ensure accuracy, and sign for the medicine.

The JIT inventory system has many great advantages. It is able to help save money and labor in their stores. The system gives Wal-Mart the ability to know what is on hand at all times. This reduces waste and storage cost. A down side of the just-in-time inventory system is that it does not take into account for theft. To account for this downfall, Wal-Mart takes a hard count of their entire inventory every three months to reconcile the inventory and starts the counts over. Another down side to the just-in-time inventory system is that it does not take into account for promotions or sales. Managers must look forward 6 weeks at a time to manually override the products they know will be going on sale (Burgin, personal note, 2015).

Wal-Mart generally prints barcodes on the bottom of receipts given to customers at the end of the checkout process. Wal-Mart recently added a value service to help customers save money called Savings Catcher® app. After check out, the customer can scan the barcode at the bottom of the receipt and the app will search to see if any of the items the customer purchased are cheaper at any other stores. If the company finds an item

is cheaper at a different store they will put the difference on an eGift card for the customer to use.

Wal-Mart does not use barcodes for inventory of merchandise only. Wal-Mart uses barcodes on their associates name badges too. Employees clock in and out with their assigned barcodes and find out what are their assigned daily tasks. Wal-Mart is able to track the movement of an employee from the barcode on their nametag. The barcode on the nametag stores all the payroll information, assignments, and length of time spend on each register. The use of the barcode system for employees reduced the HR department from a staff of 6 to 10 per store to 2 per store; a substantial cost savings motive for the company (Burgin, personal note, 2015).

Stone, Rudolph and Henry (SRH)

Another company, quite smaller than Wal-Mart, is Stone, Rudolph & Henry PLC; a medium-sized local accounting firm located in Clarksville, TN that uses barcodes in the day-to-day internal operations of the company. SRH uses barcodes to route documents using specific software by the name document. Documentation completed through purchased software that acts as a paperless storage and organizational management system. This feature allows all documents and files saved in specific folders distinguished by categories, subcategories, year, etc. The company has 4 commercial copier machines that are capable of printing, scanning, faxing, etc. These machines are refurbished and all repair/maintenance work is outsourced to Ricoh. SRH has a small technology department that is responsible for handling all of the internal operations of the business as well as providing external support to clients and

other businesses. The machines are connected to the local network and use a SMB service. This service allows for specific folders or paths to be programmed into the machine to route documents to specific, highly used, locations. This reduces the time spent scanning documents to a single location, then having to find the document, rename it and move it (Buse, personal note, 2015).

From the perspective of using the barcode routing sheet, the process is very straightforward. One gathers what needs to be scanned, puts the routing sheet on top of it, and feeds it into the tray on the copier machine. From the perspective of creating the routing sheet and knowing how it works is entirely more intricate. First, all routing sheets are created individually. One must select a client, choose to add a document, and fill out all the necessary fields. This includes creating the file name; once this is done, a routing sheet is generated. This sheet has a barcode on the top of the page and specifies all of the information used to create it, including the name and number associated with the client. The barcode numbers are five or six digits long and are randomly generated, in no particular order. Figure 1 illustrates this basic information flow using workflows of product routing sheets.

Once ready to scan and inserted onto the tray on the copy machine, the user must select a destination. In this case, the user would select the document button and press start. The document is scanned and starts the chain of reactions to process it to its final destination, which is coded in the barcode. The first place the document routed is to the scan server. Then optical character recognition (OCR) software executed for text recognition and or search. This takes the barcode, deletes the top routing sheet, changes the file name, currently in

Figure 1. Typical workflow path of the routing sheet using barcodes

a 10-20-digit number coded in the barcode, and renames the PDF as the barcode number. Next, the PDF is dropped in the export folder. CCH App Server and Document Watcher software then checks the document software to find the corresponding barcode number. This is the documents intended destination. The software applies the appropriate settings and specifications to the PDF, and transfers it to where it belongs. This process saves the company a great deal of time and money while allowing the staff to continue their work, uninterrupted. Not only are barcodes being used in industries across the country, they are being utilized across the globe.

CONTINUED SUCCESS OF BARCODES

Barcodes for European IDs

Europe has used barcodes on the back of personal identification (ID) cards for some, which is a requirement for most citizens depending on their country of residence. A person's basic information that can easily be found on the front of their identification card such as their home address, eye color, and weight among other personal factors are coded in the barcode. The type of barcode used is easily accessible by the simplest of scanners making it obtainable by anyone in the industries allowed to access this information. These industries include airport personnel, cab drivers, shops, entertainment and bars, where people live, and other places people spend money. Many identification cards have either barcodes or mag strips, while some contain both. Both of these methods are capable of coding information so that the proper authority can access it ("National ID cards," 2015). However, there are differences in size of information, cost, and security that should be taken into account when deciding which technology to use. Barcodes generally cost between US\$0.01-0.10 per barcode, while mag strips can range from US\$0.01-0.40. In terms of security, barcodes range from poor to

moderate while mag strips range from poor good. Therefore, depending on what type of information the customer are coding, whether it is common data or more personal information one would like to keep private, one should choose the technology best suited for their needs.

Barcodes for Domestic Identification Purposes

In the U.S., barcodes are typically used on selected citizen's identification cards. These cards, more commonly are referred to as driver's licenses. However, both do exist. The information coded in the barcode is similar to that of European countries including: the individual's full name, address, date of birth, physical attributes, medical impairments and donor information ("About the 2D barcode ...," 2015). Private information that is not included on the front of either card, such as social security number (SSN), face recognition template or digital fingerprint are included in the barcode. Since identification cards are not used the same in the United States as they are in Europe, less industries have access to scan the barcode, but the barcode is still as easy to decode. At least 39 states use barcodes on their IDs. The databases are independent and not shared, which is a gap in the system. There is speculation of using smart chips in identification cards in the future ("The future of RFID," 2016). This would include all of the coded information mentioned previously in addition to additional biometric identifiers. In order for this to be effective, all states would need to share a common database to ensure accurate and up-to-date information (Sammer, 2011).

Barcodes in Healthcare

Having proper healthcare is essential to human life. The simplest of mistakes made in a healthcare setting, such as a hospital, can cause someone a lot of pain and suffering. Sometimes a minor mistake, whether it is due to inaccurate labeling or performing the wrong surgery, can lead to patient

deaths. With the amount of patient safety challenges facing modern healthcare it is difficult for the industry to manage information with AIDC-embedded technologies. A constant struggle for the healthcare industry is tracking materials, inventory obstacles, and patient validation throughout day-to-day operations (Swaminathan, Chernew, & Scanlon, 2008). The use of barcodes provides the healthcare industry with an easy-to-use and cost effective solution to many of these issues (“About the 2D barcode ...,” 2015).

Barcoding can be used as much or as little as desired. The implementation of barcodes would be most beneficial to the healthcare industry if applied at a high level. Applying barcodes to multiple items within a facility will allow for the most accuracy. Barcodes can be applied to basically anything that can have a sticker attached to it. Some examples in a healthcare facility include: medication, vials (blood samples), patient wristbands at admittance, urine samples, all documents in patient charts, surgical instruments, personal belongings, and much more. Having these barcodes allows doctors, nurses, and other authorized personnel the ability to easily access information, as well as add new information about the patient or item into the system. Coupling this simple technology with RFID can have substantial benefits in the healthcare field (Seidman, Brockman, & Lewis, 2010).

Barcode wristbands, which include precise patient information, are usually generated at the point of admission and updated consistently based on the needs of the patient. Healthcare providers are able to use a mobile printer to create a barcode wristband at the patient’s bedside, which allows medication administered in a timely fashion by scanning the patient’s wristband and instantly record the patient’s medical record (Torres, 2012). Barcode technology provides certainty that the accurate treatment administered to the correct patient. Barcodes are used for workflow changes in hospitals and other healthcare practices. For instance, if a patient is transferred to another wing or department, once the barcode is scanned, the system is automatically updated. Then, when it

is time to administer medicine or for the doctor to visit, he/she can scan the barcode associated with the chart and is directed to exactly where the patient is. This reduces confusion and chaos that is brought on by the lack of communication that transpires between staff. Barcode technology allows practitioners to see all previous notations and medical information tethered to the individual and unique barcode, which is linked to each patient. Through this, staff can easily access records and see where a patient is in terms the medication cycle (Torres, 2012).

The use of barcoding in the healthcare profession has many benefits. Some of these benefits include inventory control, patient validation, and tracking materials. These benefits can be directly linked to patients, records, and overall safety. Barcodes are a key tactic to guarantee proper patient identification at the bedside (Degaspari, 2011). It is extremely important that such technology validate that the patient being treated is the right patient with the correct dosage of medication. When nurses scan a barcode, they can confirm that the item they are about to give or use on a patient is the appropriate item ordered by the doctor. They can view if they used the right item with the correct patient by scanning the barcode on the patient’s wristband and then scanning the barcode on the item. Barcode readers support the receiving and storage functions, as counting and reordering automatic, and an information system within the machine performs the calculations (Burbano, Saka, Rardin, & Rossetti, 2009).

Every healthcare facility must deal with the time-consuming process of controlling inventory. Using barcodes can speed up, as well as manage; this process is designed to automatically reorder materials when their inventory reaches a certain level. Barcode scanning systems can be useful for inventories no matter where the location and can help assure that the right supplies are available when needed. Materials are constantly traveling through a healthcare facility, from one point to the next, and it is easy to lose track of an item when it is constantly on the move. For this reason, along

it is essential to have a barcode system in these facilities. Barcodes can track an item to a specific patient and identify the physician who used it with or on the patient.

Like any other profession, healthcare services can suffer from operational problems; and, medical errors cost both lives and money (Southard, 2012). Barcode technology helps reduce these errors while not damaging the doctor/patient relationship. According to Degaspari (2011), barcodes and related technologies are not intended to replace human interaction with the patient, but they are redundant identifiers that are more fail-safe than many other approaches.

As previously mentioned, barcode scanners are used for medication inventory management and tracking, as well as for patient/drug identification/verification when administering medications at the point of care to prevent errors and increase patient safety. Anti-microbial products are particularly important in these activities. Scanners are useful for tracking bar-coded medical equipment inventories (McBride, 2012).

Advancement in technology reduces the chance for error, but as stated previously, errors cannot be completely eliminated. 2-dimensional barcodes can withstand a higher degree of damage before they are rendered useless. The question whether 2-dimensional barcodes are reliable or not, seems to be in the favor of it being reliable. The software needed to scan the barcode can be downloaded on smart phones, Android cell phones and the Apple iPhone.

The future of 2-dimensional barcoding in healthcare is very promising. The healthcare industry has already caught on to the benefits it would provide. Many hospitals are transitioning from linear to 2-dimensional barcode technology. The barcode historically has had success in other industries; many predict it will have a similar outcome in the healthcare industry. Many, doctors, nurses and patients alike, welcome the change it would provide though it is not possible to completely eliminate all dangers in the healthcare field. Two-dimensional barcoding will help prevent many mishaps and solve some

major problems. Its major competitor would be RFID, but as explained earlier in this chapter, 2-dimensional barcoding has the advantage since it is cheaper than RFID and better fit for tasks in which an object is moving and the person is not.

CONCLUSION

Barcodes are machine-readable codes; usually placed on a product, that have been around for over 50 years. Barcodes can be used in a variety of industries for an unlimited number of uses. Generally, barcodes exist in a linear or 2-dimensional format. They are the best choice of coding information in terms of costs, but not security. Barcodes have the ability to improve any process, and can be an asset to the largest and smallest of businesses. Barcodes are making more information more easily accessible, as discussed in connection with identification cards. Lastly, the use of two-dimensional barcodes in healthcare will be very beneficial and cost effective for the future of the industry. In hospitals especially, the benefits barcodes provide could possibly save a patient's life.

FUTURE RESEARCH DIRECTIONS

Consequentially, the best option a manufacturing company can choose is to implement AIDC technologies in combination with other strategies such as total quality management (TQM) and barcodes as a backup technology to reduce errors. The efficiency and effectiveness are good goals for using any intensive AIDC-intense technology when developing any new ideas for a production process. The authors made this an important focus of the study, which was very important. Then the two factors were linked to manufacturing processes such as supply chain management, which proved to aide in the research. The implementation of such technologies ultimately is still negotiable, but there are universal advantages of both types of identification, with barcodes well entrenched.

KEY TERMS AND DEFINITIONS

Barcoding Technology: A long-term and very reliable type of AIDC technology, it is known for its very accurate and economical approaches to identity products and machine-readable information from a variety of manufactured goods and services. Most barcodes use a type of standardized bars and spacing coding or symbology, certified by an international standards body (GS1 System). This system provides for the universal global acceptance of many types of barcodes designed for a variety of shipping and identification applications. Example barcode formats that are in common use today include EAN/UPC, GS1 DataBar, GS1-128, ITF-14, GS1 DataMatrix, GS1 QR Code and Composite Components.

Personally Identifiable Information (PII): Personally identifiable information (PII) refers to all information, including personal financial and healthcare information that is traceable to an individual customer or patient.

RFID-Embedded Technologies: RFID technologies are types of automatic data capture techniques that use a combination of active and passive senders and receivers to collect and store codified information for further uses. The implementation of such technologies should lead to improved managerial and/or supply chain performance. On the surface, there appears to be few drawbacks to implementing such technology into a production process, assuming it enhances performance and improves output of the product. The main issues surrounding the RFID applications are whether the initial costs and labor required to utilize this technology are worth it, and will result in a positive outcome of revenues.

Becoming Smart, Innovative, and Socially Responsible in Supply Chain Collaboration

Goknur Arzu Akyuz

University of Turkish Aeronautical Association, Turkey

Guner Gursoy

Okan University, Turkey

INTRODUCTION

Collaboration is rapidly emerging as an essential part of doing successful business (British Retail Consortium 2014). It has become the key to effectiveness, agility and competitiveness within the global dynamics of digital economy where competition is no longer between organizations but between supply chains (SCs), (Kim, 2006; Trkman et al., 2010; Akyuz & Gursoy, 2010, Cao & Zang, 2013; Lehoux, D'Mourse & Langevin, 2013). Because of various concerns; including rising resource costs, financial shocks, disruption in SCs, changing consumption patterns, emerging new business models and environmental issues; organisations are forced to manage an ever-changing business context. Such systemic challenges are evidently driven by multiple factors, and they cannot be resolved by any single organisation. Collaboration, two or more organisations working together to address common problems or develop opportunities, has the potential to create an overarching change for long-term sustainability. Hence, enterprises are turning to collaboration more and more to address problems too complex to deal with on their own (British Retail Consortium, 2014).

Collaboration in the context of SC is an amorphous and meta concept that has been interpreted in many different ways by both organizations and individuals. Academic definitions mainly focus on the business-to-business (B2B) internet-based technologies; while practical definitions have a wider scope (Wang, 2006).

Arshinder & Deshmukh (2008) list collaboration definitions in their study as: (a) joint planning, joint product development, mutual exchange of information and integrated information systems, cross coordination on several levels in the companies on the network, long-term cooperation and fair sharing of risks and benefits, (b) two or more independent companies working jointly to plan and execute supply chain operations with greater success than when acting in isolation, (c) a win-win arrangement to provide improved business success for both parties, (d) a strategic response to the challenges that arise from the dependencies.

Obviously, the concept is multi-dimensional, going far beyond simple transactional integrity among systems, and involving strategic-level exchange of information and decision making. It is also well-proven to be directly related with various ideas such as SC cooperation, integrity and visibility. In this context, both coordination and integrity refer to tight process couplings among SC partners. The term integration means the unified control of different processes, putting more emphasis on central control and ownership (Cao & Zang 2011), and collaboration puts more emphasis on governance through relationship.

The related literature provides sound support for the benefits accruing from collaboration; for the positive correlation with SC performance, and critical SC capabilities such as agility and flexibility (Akyuz & Gursoy, 2010; Sanders, 2007; Arshinder & Desmukh, 2008, Cao & Zang 2013, Wiengarten *et al.* 2013; Kim & Nettesine, 2013,

Cao & Zang 2011). When organisations come together, they can combine their resources, knowledge, insights, creativity and collective leverage to create radical change in critical business areas. Undoubtedly, process of learning to collaborate may take time; it may seem complex and unfamiliar and require passion, commitment and investment; but the achievements can be significant (British Retail Consortium 2014).

In this chapter, the confusion, interchangeable and ambiguous use of collaboration terminology is explored via literature taxonomy, and a collaboration maturity model is introduced. In the next section, the relationships and precedence among collaboration-related terminologies, as well as existing maturity models are discussed by highlighting the ambiguities and interchangeable use. Then, the concepts of smartness, innovation and corporate social responsibility (CSR) are discussed as the key themes for the current understanding of SC collaboration. Motivated by:

1. The lack of consensus on terminology;
2. Maturity stages of the existing maturity models; and
3. The critical importance of smartness, innovation and CSR, a conceptual model is developed based on the maturity model offered in Akyuz, Gursoy & Celebi (2014).

The conceptual maturity model:

1. Provides a mapping of the model stages onto various SC processes;
2. Offers process-based, staged and precise descriptions of chain-level evolution of collaboration;
3. Covers advanced forms of system-level collaboration; and
4. Explicitly treats smartness, innovation and CSR in relation to CSR.

Background - Terminology and Existing Maturity Models

Extant literature related with SC collaboration highlights that it is closely interrelated with the terms: communication, cooperation, coordination, integrity, partnership, visibility, trust and synchronization. The terms of “cooperation”, “coordination”, “collaboration” and “integrity” are interchangeably used and sometimes refer to different evolutionary stages along a continuum of dependency among SC partners. Akyuz, Gursoy & Celebi (2014) provides a comprehensive discussion on this confusion in terminology.

Thompson & Sanders (1998) put forward the continuum of ‘competition→ cooperation→ collaboration →coalescence’, considering the term “*coalescence*” as the highest level of integrity and joining forces. Kim et al. (2004) refer to the Speakman et al. (1998), which treat “cooperation”, “coordination” and “collaboration” as three different stages to define the transition to “collaboration”. In their classification:

1. Cooperation refers to long term contracts;
2. Coordination is associated with information linkages; and
3. Collaboration is associated with joint planning, integration and sharing.

The distinction of “intra- and inter-organizational coordination” is emphasized while discussing the opportunities of the internet-based information systems (Akyuz & Rehan, 2009; Chen & Chen, 2005; Arshinder & Deshmukh, 2008; Kelle & Akbulut, 2005). This transition emphasizes that ability to cooperate leads to coordination, which in turn evolves into the collaboration across SC partners. “Joint planning” appears as a critical ability which determines collaboration, and the term “integrity” is highlighted.

Based on Christopher (2005) and Werner (2008), Ivanov & Sokolov (2010) define the organizational levels as ‘open market negotiations→cooperation→communication/integration→coordination→collaboration’. In this categorization, collaboration is again treated as a broader and enhanced concept than cooperation, integration and coordination. However, it is striking that communication is used interchangeably with integration, the idea which the authors do not agree and also contradicts with Speakman et al. (1998). The authors hold the opinion that the integrity concept is far beyond “linkages” and “communication channels”.

Based on Cooks & Delattre (2001), Hoppe (2001) uses the term “coordination” and discusses four stages of coordination as ‘conventional’, ‘integrated’, ‘collaborative’ and ‘optimally coordinated’. The term “coordination” used is defined in generic, with a broader coverage, and the terms “integrity” and “collaboration” are used as “stages” along the evolution. Stages are defined starting from a firm-centric, conventional structure to first “externally integrated” supply chain-centric, and then strategically collaborating structure. It should be noted that “optimal coordination” is mentioned at a later stage, leaving the term “chain-centric collaboration” at an earlier one. This is quite controversial because collaboration appears as a “lower” phase of optimal coordination, contradicting with both Speakman *et al.* (1998), and Ivanov & Sokolov (2010). In this context, the term “optimal” is also controversial, since it raises question of the construction form of optimality.

Ayers (2010) mentions a 3-level classification with respect to the “degree of collaboration”. Collaboration is treated as a higher level than coordination, involving process collaboration, joint planning and scheduling and win-win partnership across the network. Ayers (2010) also refers to the collaboration roadmap developed by collaboration technical team working on the Supply Chain (SCOR) model. In this roadmap, levels are defined

in the order of increasing intensity of information exchange and uncertainty as follows:

1. **Data Exchange Collaboration:** Where partners exchange information as required (one-way or two-ways), mainly to complete day-to-day transactions;
2. **Cooperative Collaboration:** Where partners share systems and tools so that all have access to information simultaneously;
3. **Cognitive Collaboration:** As the highest level requiring “joint, concurrent intellectual and cognitive activity” between partners, and embracing information sharing for joint decision-making. This roadmap considers “collaboration” as the main construct, treating coordination as a prior level to cooperation, and classifying them again as “degrees of collaboration”.

Jespersen & T.Skjott-Larsen (2005) discuss the SC integration levels in terms of complexity and SC relations. The proposed relationship defines the levels of ‘internal integration’, ‘coopetation’ and ‘synchronization’. This classification emphasizes the transition from functional to networked structures along with increased SC complexity. Although “integrated business processes” refer to external integrity, the terminology “external integration” does not appear explicitly in their study.

The “Integration” concept is also emphasized in Campbell & Sankaran, 2005; Xu et al., 2005; and Muffato & Payaro (2004) as part of the staged evolution of an organization. Emmet and Crocker (2006) prefer stages of “functional silos/ internal integration/ external integration”, based on the scope of integrity.

It is important to note that the distinction of “internal” versus “external” integration is frequently encountered in literature. Internal integration refers to “the degree to which a firm can structure its organizational practices, procedures and behaviors into manageable processes”, mainly involving data and information system integration

Figure 1. Supply chain objectives versus supply chain integration (Based on Ross, 2003)

through the use of Enterprise Resources Planning (ERP) systems, cross-functional cooperation and elimination of the functional silos (Zhao et al., 2011). External integration refers to the “*degree to which a firm can partner with its key supply chain members to structure their inter-organizational strategies, practices, procedures and behaviors into collaborative, synchronized and manageable processes*” (Zhao et al., 2011), information sharing, synchronized planning and joint problem resolution being the main themes. Ross (2003) discusses SC integrity using the “internal” versus “external” distinction along with extending level of network integrity and interoperability, leading to the e-supply chain formation, as depicted in Figure 1.

In this regard, various other literature items fully support the idea of ‘internal integrity being the necessary prerequisite for external integration’ (Rosenzweig et al., 2003; Stevens, 1989; Vickery et al., 2003; Akyuz & Rehan, 2009; Akyuz & Gursay,

2010). They support the transition from functional, internally-focused structures to extended architectures that can communicate and collaborate beyond the enterprise. Verdecho et al. (2011) emphasize this idea mentioning that “*if the collaboration is to succeed, internal collaboration has to be aligned with external collaboration*”. Clearly defined and integrated intra-enterprise process definitions become vital for being able to move to higher levels of integrity. Thus, standardizing, streamlining and coordinating the internal functions properly represent a critical stage of evolution (Akyuz & Rehan, 2009). Integrity of the internal processes are ensured as the isolated internal silos of functional information are broken down and enterprise-wide applications are efficiently put in place. Only after this stage that external integrity considerations and collaboration with other SC partners can be in question. Consequently, internal collaboration becomes a prerequisite for successful collaboration among partners. Zhao et al. (2011)

Table 1. Comparison table for various maturity models

	Maturity Levels	Description
Computer Sciences Corp. (CSC) Framework based on (Poirier and Quinn 2003)	• Functional integration • Logistics integration • Inter-organizational processes integration • Collaborative initiatives • Complete join, collaboration	Defines maturity levels in terms of scope of integration/collaboration , starting from functional integration and extending to complete join.
Business Orientation Maturity Model by Lockamy & Mc Cormack (2004)	• Ad-hoc • Defined • Linked • Integrated • Extended	• A SCOR-based model • Starting with the ill-defined processes within an enterprise, stages are defined in terms of degree and extend of collaboration for various processes. • Highest level of integrity corresponds to the 'extended' level (multi-firm networks are strongly coupled by trust and mutual dependency). • Developed as a common language for benchmarking purposes, this model is critical as being SCOR-compliant, providing a grade scale for classifying the company into one of these classes.
Capability Maturity model integration- CMMI www.sei.cmu.edu/cmmi	• Initial • Managed • Defined • Quantitatively managed • Optimizing	• Ability to include quantitative approaches is defined as a maturity level. • Contains a set of best practices and roadmap.
Classification by Bendoly and Jacobs (2005)	• Fundamentals • Cross-functional teams • Integrated enterprise • Extended supply chain • Supply chain communities	Defines a 5-stage evolution model extending to 'SC communities'.
PMMM (Kerzner Project Management Maturity model) (Kerzner 2001, Ayers 2010).	• Common language • Common processes • Singular methodology • Benchmarking • Continuous improvement	5 stages are defined in terms of organizational awareness, management support, process discipline and motivation.
Pache and Spalanzani (2007)	• Intra-organizational maturity • Inter-organizational maturity • Extended, intraorganizational maturity • Multi-chain maturity • Societal maturity	5 stages are defined with a focus from intra to societal maturity.
SCOR Maturity, based on Cohen and Russel (2005).	• Functional integration • Internal integration • External integration • Intercompany integration	Four stages, extending from functional integration to intercompany integration.

(Based on Akyuz, Gursoy & Celebi, 2014)

emphasize the consistent findings in this line, provides empirical support arguing that internal integration enables external integration, and highlights that: “*organizations must first develop internal integration capabilities through system, data and process-integration before they can engage in any meaningful external integration*”.

Consequently, this is a staged evolution and collaboration-related maturity models present in the literature try to classify and define various maturity levels in terms of the terminology “integration” and “collaboration”. Table 1 shows a comparison table for different maturity models presents in the literature clearly indicates and

*Figure 2. Dependence and evolutionary sequence among different concepts
(Based on Akyuz, Gursoy & Celebi, 2014)*

compares the main stages used in these maturity models.

In this table, CSC (Computer Sciences Corporation) framework prefers the terminology “integration” and “collaboration” for defining stages. Business Orientation maturity model by McCormack & Lockamy (2004) use the wordings “linked”, “integrated” and “extended”. It is evident that collaboration is generally treated at a higher level than integrity. Although different naming and terminology is present, in all of the above-mentioned literature items a shift is observed from functionally-oriented and internally-focused structures to extended architectures in which communication and collaboration goes beyond the enterprise.

Collaborative Planning, Forecasting and Replenishment (CPFR) model by Voluntary Inter-industry Commerce Standards (VICS) Association is another key model related to SC collaboration (VICS, 2004, Seifert, 2003). The model is not cited as a “maturity model”, but rather it offers a process-based philosophy, and represents the ability to integrate planning, forecasting and replenishment-related activities across partners. It refers to tight couplings for the entire material management cycle, and utilizes the term “collaboration”. Its scope covers whole set of planning, forecasting and replenishment activities and it represents a significant stage for the integrity and restructuring of external relationships across partners.

All of the above discussion highlights that there is no clear consensus on the use of the terminology “coordination”, “collaboration”, “integration” and “cooperation” in literature. Apparently, developments in the SC domain lead to the search for and the creation of new terminology. This inconsistency is inevitably reflected in the naming and definitions of the maturity stages and further complicates the matters. Figure 2 clarifies the terminology and describe the dependence and evolutionary sequence among the concepts.

In this diagram:

- Communication forms the base for obtaining a certain level of “cooperation”, resulting in “coordination”. This is in compliance with the transition steps of Spekman et al. (1998);
- Continued “cooperation” and “coordination” evolve into the ability to “collaborate” at various processes. Meanwhile, visibility, transparency, synchronization and integrity among the partner systems continue to increase;
- Integrity covers architectural, procedural and organizational integrity both within and across the partners. This is in compliance with “internal integrity”/ “external integrity” distinction as well as accepting “internal integrity as a prerequisite to external integrity”. As external integrity in-

creases, higher levels of collaboration are achieved among actors;

- Visibility, generally used as synonymously with transparency, also increases in parallel with the level of integrity and synchronization. As partner systems start to operate in a more and more integral and synchronous manner, better visibility for entire set of processes is obtained;
- Transition is associated with increasing degree of partnership and trust.

SMART, INNOVATIVE AND SOCIALLY RESPONSIVE COLLABORATION

In the light of this basic background and evolutionary process described in the previous section, it is evident that integration and collaboration are the key themes characterizing the recent SCM practices. In SCM context, it is observed that being smart, innovative and socially responsible in collaborative activities are essential for success. This section discusses these three main themes in relation to SC collaboration.

Smart Collaboration

With all the dramatic advances and opportunities offered by technology, SCs turned into digitized smart value networks (Accenture 2014, Robinson 2015). We are witnessing the Industrial Revolution 4.0, which is characterized by:

1. Ubiquitous connection of people, things and machines;
2. The increasing digitization and interconnection of products, value chains and business models;
3. Integrated analysis and use of data with increasing transparency (Strategy & PwC 2014).

This is a totally new level of organization, control and visibility for the entire value chain

over the lifecycle of the products, revolutionizing the product portfolios, performance relationships, and resulting in innovative business processes. Piecemeal digitization of SC elements is seen to be counterproductive, and re-imagining the SC as an integrated, smart and value-creating supply network is essential. Digital technology renders the traditional SC models obsolete, facilitates an unprecedented degree of integration and collaboration across partners, and enables the handling of processes across SC partners in a smart and autonomous manner (Accenture 2014). Various recent concepts such as mobile technology, wearable technology, robot technology, autonomous vehicles, unmanned aerial vehicles, drones, automated cranes, low-cost sensors, advanced manufacturing systems, cloud computing, big data, 3D printing, Industry 4.0, and Internet of Things (DHL Report 2014, Deloitte 2015, Raconteur.net, Strategy & PwC (2014), Dimensional Research 2015, Robinson 2015) elevate the opportunities of integration and collaboration across partners to a totally new dimension. Today's SCM talks about smart factories, smart buildings and smart mobility with build-in intelligence, real-time capabilities providing end-to-end visibility. All logistics activities are handled by more and more intelligent systems (Raconteur 2015, Robinson 2015). People, trucks, containers and vehicles become increasingly autonomous and intelligent, working in perfect synchronization. 3D printing continues to be a hotly debated topic, with the prediction that as 3D printing starts to become a supplementary way to manufacture parts, a new complexity will be added to logistics activities. It would be necessary to smoothly integrate and orchestrate the logistics flows of traditionally manufactured parts and parts produced by 3D printing. This undoubtedly offers tremendous opportunities as well as challenges for the entire logistics cycle, completely reshaping the supply chains. All these technological opportunities make the SC more responsive and more demand-driven (Robinson 2015), and consequently, we are witnessing connected, complex, dynamic, digitized,

smart and scalable value creation networks (Kelly & Marchese 2015).

Within this technology-intensive character, enterprise application integration platforms of proven software vendors assume a vital role. These software suites provide seamless, end-to-end SC integration and visibility across partners for all the processes, including all logistics activities. In this regard, cloud technology offers tremendous opportunities for SC partners to access such platforms on the cloud without a prohibitive initial investment. This makes these software suites accessible even for small and medium sized enterprises, providing them with superb visibility and business analytics.

Consequently, the ideas of inter-enterprise integration and collaboration turned into smarter systems connectivity with the key capabilities of built-in business intelligence and analytics, autonomy, and integrated planning and analysis (Dimensional Research 2015, Strategy & PwC 2014). Hence, SCs will transform into smart, collaborative and value-creating networks with Industry 4.0 transformation.

Innovative Collaboration

Together with all these unprecedented technological advances, another key aspect for the success of the entire SC is to ensure that partners can develop innovative products, services and business models. Hence, collaborative innovation is the next big idea that allows players across the value chains to participate in the emergence of new collaborative business models. Based on solid foundations of intrapreneurship, collaborative innovation is the engine of modern and agile organizations capable of creating new capacity and pioneering radical new ideas (World Economic Forum 2015). Just like being a central theme to material management activities, collaboration is also central to innovation, since:

1. It increases the chances of associations between ideas resulting in innovative combinations;

2. Collaborative feedback accelerates the inevitable iterations;
3. It results in more connections to people to push a good idea forward;
4. Teams provide the energy and help overcome resistance; and
5. Collaboration helps ideas reach implementation.

Hence, across-partner collaboration on product design and development evolves into joint innovation creation ability in time. Undoubtedly, this ability is a competitive advantage in the harsh, global and chain-level competition continuously demanding faster product development cycles and new product ideas (Dance, 2008). World Economic Forum (2015) argues that companies that can manage collaborative innovation creates value by:

- Acknowledging the value of collaboration at strategic level across partners;
- Explicitly defining the objectives, openly declaring the intent and ensuring executive commitment at multiple levels from multiple partners;
- Defining the value and resources to be contributed by and brought to partners;
- Creating joint awareness and enabling joint management of the potential innovation and risks related with new product development;
- Identifying in advance at which stages and with which protections sensitive commercial information could be revealed to a partner;
- Ensuring that collaboration objectives and processes are aligned for maximum mutual gain.

Socially Responsible Collaboration

The concepts of sustainability, environmental sensitivity and corporate social responsibility (CSR) also became the key themes gaining utmost importance in SC collaboration. In this context,

Corporate Social Responsibility is the continuing commitment by business to contribute to economic development while improving the quality of life of the workforce and their families as well as of the community and society at large (The World Business Council for Sustainable Development). As it is evident from this definition, CSR is a broad concept which involves multiple stakeholders; and multiple issues. It is directly related with strategy, sustainability, environmental sensitivity, business ethics, value creation, service quality, customer retention and brand image of an enterprise (Wu 2006, Quarshie, Salmi and Leuschner 2016, Whitley and Willcoks 2011). More and more enterprises start to initiate various CSR programs encompassing a wide variety of subjects such as community involvement and development, consumer issues, fair operating practices and environmental protection, among others. Many concepts related with economic, environmental and social concerns are being treated under the umbrella term “CSR”. Thus, information exchange and integrating efforts across the SC partners towards meaningful CSR initiatives will create a chain-level competitive advantage (GCI-Capgemini 2016).

As a result, the ideas of smartness, innovation and social responsibility have to be addressed in any recent model related with SC collaboration concept.

COLLABORATION MATURITY MODEL

In the light of the previous two sections, main focus of this study is to develop a conceptual maturity model for SC collaboration. This section introduces a conceptual and 8-staged maturity model for defining the evolutionary phases of collaboration. This model is an enhanced version of the maturity model given in Akyuz, Gursoy & Celebi (2014), addressing the smartness, innovation and CSR concepts as well.

The model described incorporates: detailed description of the collaboration phases, system

complexity, scope of collaboration and matching of the stages with the spectrum of “communication → cooperation → coordination → collaboration” (given in Table 2), and mapping of different SC processes onto stages (provided in the Figure 3) by incrementally adding new ones at each stage.

The maturity model has the following characteristics:

- It considers the transition: “functional → enterprise → SC → SC network”, representing the move from functional silos within the enterprises to SC networks with complex interactions across partners;
- It is in compliance with:
 - The distinction “internal” versus “external” integration, and the necessity to obtain internal integrity as the prerequisite of external integrity;
 - The general trends observed in the maturity frameworks;
 - The presence of ERP systems as a foundation for improving integrity levels;
 - The idea of extended enterprise;
- It addresses advanced and strategic forms of collaboration. Various systemic efforts such as collaborative quality management, collaborative performance and risk management are integrated in this model structure;
- Very recent concepts such as collaborative innovation, collaborative CSR and smart collaboration are embedded in the model.

In this model, material management processes are considered as the “core processes” on which further ERP functionality is built to achieve internal integrity. The model considers complete ERP functionality at “*Internal integration level 2 (stage 2)*” by covering the processes such as costing, human resources and budgeting. The rest of the levels are externally oriented and supply chain-centric. Existence of an ERP backbone at this level ensures the achievement of a degree of

Table 2. Maturity model phases

Stages	Collaboration Level	Complexity	Scope of Collaboration	Level of Interaction Internal External	
1	Internal Integration Level 1	Functional	• Intra-departmental level. • Material management oriented. • Includes capacity planning. • Closed loop planning and decision cycle. • Represents the integration of purchasing, planning, inventory management and production.	Cooperate	Communicate
2	Internal Integration Level 2	Enterprise	• Intra-enterprise level. • Closed loop management of entire set of enterprise resources. • Includes the integration of costing, accounting, budgeting, quality management and HR processes.	Coordinate	Cooperate
3	External Integration Level 1	Supply Chain	• Inter-enterprise level including both suppliers and customers. • Material Management and Logistics oriented. • Initial ERP add-ons such as e-procurement. • Initial B2B integrity.	Coordinate	Cooperate
4	External Integration Level 2 (Extended Enterprise)	Supply Chain	• Inter-enterprise level including both suppliers and customers. • Extended view of the enterprise, extended ERP (Further ERP add-ons- SRM and CRM, mainly operational and analytical). • Further internal integrity with MES (Manufacturing Execution Systems) and APS (Advanced Planning and Scheduling) extensions. • Strategic enterprise management with corporate performance and risk measurement, consolidated financial reporting. • The concept of “smartness” starts to develop.	Collaborate	Coordinate
5	Collaboration Level 1	Supply Network	• Inter-enterprise level over a network. • Long term partnerships & visibility for inbound & outbound logistics • Collaborative planning, forecasting and replenishment. • Further capabilities like APO. • Joint problem solving, decision making, dispute resolution & action taking. • Increasing smart decisions across partners.	Collaboration	Collaboration
6	Collaboration Level 2	Supply Network	• Inter-enterprise level over a network. • Collaborative CRM and Collaborative SRM. • Strategic collaboration with customers, suppliers and logistics partners. • More strategic business intelligence and smarter decision making in SRM and CRM.	Collaboration	Collaboration
7	Collaboration Level 3	Supply Network	• Inter-enterprise level over a network. • Collaborative Product Design and Development. • This concept also includes the collaborative innovation. Ability to create innovative solutions • Sharing of mission-critical design data and innovative ideas	Collaboration	Collaboration
8	Collaboration Level 4	Supply Network	• Inter-enterprise level over a network. • Scope of collaboration extended to systems assurance and development, including • Collaborative Performance Management, • Collaborative Risk Management, • Collaborative Project Management, • Collaborative Quality Assurance, • Collaborative Strategy development, • Collaboration in Sustainability efforts & various CSR activities.	Collaboration	Collaboration
	Coalescence	Supply Network	• Perfect unification as a whole. • Perfect join of the forces. • Total integration of the systems.	Extreme Collaboration	Extreme Collaboration
	Virtual Network	Supply Network	• Perfect reliance on IT infrastructure. • Temporary structures with minimal or no existent resources.	Extreme Collaboration	Extreme Collaboration

(Based on Akyuz, Gursoy & Celebi, 2014)

Figure 3. Mapping of the supply chain processes to maturity stages
(Based on Akyuz, Gursay & Celebi, 2014)

“internal integrity” before any further systematic external integration efforts.

The model details are explained for the subsequent levels as follows:

- Procurement-oriented ERP add-on applications (such as e-procurement, e-invoicing, e-fulfillment) and initial B2B integrity are positioned in the model at “*External Integration Level 1*” (*stage 3*). This overrides the transaction-oriented and restricted understanding of e-procurement, and places the procurement function at the heart of the external integration;
- *External Integration Level 2* (*stage 4*) is characterized by increasing internal and external integrity, with further add-ons such as Manufacturing Execution Systems

(MES), Advanced Planning and Scheduling (APS), Supplier Relationship Management (SRM) and Customer Relationship Management (CRM). Operational as well as analytical SRM and CRM functionalities are involved. The ideas of “smartness” and “business intelligence” start to develop at this stage. Various smart technologies to capture instant data from manufacturing systems, customer side and supplier side are integrated with the backbone ERP systems. On-line, real-time business analytics enhance managerial decision making;

- *Collaboration Level 1* (*stage 5*) is defined to be totally compliant with Collaborative Planning, Forecasting and Replenishment (CPFR) model, and represents the joint planning, forecasting and replenishment

ability by taking joint resource constraints into consideration. This level is a critical stage for the network. Partners learn how to engage in joint problem solving, dispute resolution and exception handling across the complete planning, forecasting and order fulfilment cycle;

- *Collaboration Level 2 (stage 6)* provides strategic collaboration at SRM and CRM functions. Long term strategic partnership establishment is critical at this stage. Further business intelligence and smarter decisions for the customer and supplier sides are enabled;
- *Collaboration Level 3 (stage 7)*, extends the collaboration scope beyond CPFR to cover collaborative research, product design and development, and collaborative innovation. At this stage, all the design, customer and supplier-related data and information, as well as related plans and forecasts, are shared. Supply chain partners are able to create innovative ideas. This is compatible with the collaborative innovation idea offered in Whitney and Willcocks (2011). Undoubtedly, this level of transparency requires significant level of mutual trust among partners;
- *Collaboration Level 4 (stage 8)* represents a highly strategic degree of collaboration and alignment among partner systems for collaborative systems assurance and development. This level involves joint efforts for the areas such as collaborative quality management, collaborative performance and risk management. This necessitates sharing of strategic, system-level and confidential information and knowledge, which is clearly far beyond sharing forecasts, plans and replenishment data among partners. Mission-critical design data, joint risk assessment and performance measurement metrics and evaluations are some examples. At this stage, partners gain the “joint systems development” ability and

engage in joint business process reengineering. They also engage in collaborative strategy development, and reach a high level of strategic alignment for their long-term partnerships and for sustained collaboration. Efforts at this stage has a systems assurance and sustainability perspective. Collaboration scope is thus further broadened to encompass strategic corporate social responsibility (CSR) activities.

In this ordering, various applications like e-procurement, e-invoicing, SRM and CRM are treated at stages 3 and 4, in line with the well-supported “ERP add-ons” assertion in literature (Bendoly & Jacobs, 2005). The procurement relations are the first and the most fundamental external links to be initiated before any other add-ons, as commonly supported by the literature (Akyuz & Rehan, 2009; Leonard & Cronan, 2005; Kothari et al., 2007; Chang, Tsai & Hsu, 2013). Therefore, e-procurement (at stage 3) is listed before the other add-ons.

It is evident that the scope of collaboration defined in CPFR is beyond the capabilities of ERP add-ons as well as the operational and analytical levels of SRM and CRM. This broader scope demands systematic jointness and dispute resolution for the overall planning, forecasting and replenishment cycle (Seifert, 2003; Wang, 2006). Thus, stage 5 of the proposed model appears as a higher stage in compliance with CPFR. Capabilities mentioned at stages 6, 7 and 8 represent a collaboration scope beyond CPFR cycle, defining strategic collaborations at SRM, CRM, system and product development (Akyuz, 2011; Jayaram & Pathak 2013), joint BPR, performance and risk management areas.

Evidently, stages 4-8 demand strategic levels of information exchange, reporting and business analytics. Big data concerns (data warehousing, big data analytics, data security, and authority and authentication issues among multiple infrastructures) are increasingly amplified along these stages, starting mainly at stage 4.

Stage definitions “coalescence” and “virtual network” are included in the model as two extremes along the evolution.

“Coalescence” is the ultimate unification of the network partners and total integration of the systems. It is literally “sharing a common faith” among the partners, and “ability of acting as a single organism when needed”. This understanding is in compliance with the assertions of Thompson & Sanders (1998), positioning the term at the extreme along the path of evolution.

“Virtual network” is another extreme, generally representing temporary and rather volatile structures established on an ad-hoc basis with minimal or no level of physical resources. It widens the collaboration and business opportunities by relying on IT infrastructure and rapid reconfiguration capabilities. A general consensus is observed in the literature as to the temporary nature and reliance on IT for this term (Camarinha-Matos et al., 2009; Noran, 2009; Poirier & Quinn, 2003). Although they represent very dynamic and agile structures, the authors hold the opinion that the transient nature with minimal physical existence conflicts with the idea of long-term collaboration in business processes. Such a structure also neglects the soft aspects of the collaboration, such as corporate culture and mutual trust. With these characteristics, it is not highly probable that the scope of collaboration will be extended to collaborative product design and development, collaborative performance, risk and quality assurance for this type of organizational structure. Therefore, virtual enterprises not necessarily reach collaboration levels 2, 3 and 4 in terms of scope, or not necessarily lead to coalescence. Because of these characteristics, it is preferred to treat the term as an “extreme” stage in the model.

The term “value chain” is not included in our model. The concept of value creation for all the SC partners is inherently embedded throughout all stages to a higher or lesser extent. Value is being created starting even at the early stages of SC formation. For this reason, it is preferred not to use the term “value chain” to refer to a certain

specific maturity level. Consequently, collaboration level 4 (collaborative systems assurance and development) represents one of the highest levels to be reached in this structure.

The following parallelisms can be established between the stages of the proposed maturity model and the literature: (a) They coincide with the assertions of Cooks & Delattre (2001), as well as Jespersen & Skjott-Larsen (2005). (b) The “cognitive collaboration” stage of the roadmap from transactional to cognitive collaboration mentioned in Ayers (2010) corresponds to level 8 of the proposed model. (c) “Extended” stage (level 4) is compatible with the classification of Bendoly & Jacobs (2005).

Contribution and Strengths

The following issues stand out as the major contributions and strengths of the developed maturity model:

- The concepts of communication, cooperation, coordination, collaboration and integrity are jointly treated, clarified and tied up to a staged maturity model. The clarification of the concepts is represented in the Figure 2. We intend to contribute to the literature by eliminating the confusion in terminology, by establishing a common understanding and a common ground for future discussions in the SC field;
- Clear maturity stages are defined in compliance with the ideas of “beyond-ERP”, “ERP add-ons”, “internal integrity first”, “extended enterprise”, and the general trend followed by the existing maturity models. The proposed model provides more comprehensive and extended stage definitions when compared with the models existing in the literature. These refinements and definitions are significant contributions to SC research. The model contains 8 evolutionary and 2 extreme levels. Stages after collaboration level 1 (Stage 5) go beyond

the planning and material management oriented scope of CPFR. Hence, CPFR is extended after stage 5. This extended region is undefined in the maturity models given in literature, hence it is a contribution. The model provides the treatment of two extreme stages, virtual networks and coalescence, within the maturity model context as well. Since these recent terminologies in the literature are not treated systematically in relation to a staged maturity model, this is again a contribution;

- The model contains precise mapping of the maturity stages onto SC processes. Detailed definitions of the main processes which are incrementally added at each stage to the collaboration scope are provided in our model. The Figure 3 (mapping diagram), only Business Orientation Maturity Model by Lockamy & McCormack (2004) attempts to establish relationship with SC processes via SCOR methodology. However, its process coverage is limited with the processes included in SCOR model. The other models do not provide any relationship with the maturity stages and the SC processes. Hence, the proposed model is a contribution by establishing a precise mapping between the SC functions and the maturity levels;
- Collaboration is treated at all processes in the proposed model, including collaborative design and development, collaborative performance and risk management, collaborative project management, collaborative quality management and collaborative CSR. Process coverage of the existing models are mainly material management oriented, and they do not specifically include the processes mentioned at stages 6, 7 and 8, which are recent, advanced and more strategic forms of collaboration. This provides full process coverage in terms of collaboration scope. This is another contribution to SC literature, since existing

maturity models do not have such a broad and systematic coverage related with these advanced and strategic forms of collaboration. Hence, collaboration is treated at all inter-temporal dimensions (operational, tactical and strategic) for all processes in this model;

- Recent concepts of smartness, collaborative innovation and collaborative CSR are treated in this model.

Collaboration Roadmap

With the above-stated contributions and strengths, maturity stages and the evolutionary path, the model provides a managerial roadmap as well as a sound base for managerial decision making from a variety of perspectives:

1. **For Determining Collaboration Maturity Level of a Single Enterprise with Respect to the Levels Defined:** When supported by real-world field applications, stage definitions can be utilized as a base for critical decision making. As-is status of the enterprise can be determined with respect to these defined levels via questionnaire-based field studies and structured meetings designed in compatibility with the stage definitions of the maturity model. A standardized grading scheme and thresholds for the maturity levels can be determined for an enterprise. When the enterprise score is compared with the threshold levels, positioning of an enterprise can be established. In this regard, a variety of scales and different scorings can be utilized in connection with defined maturity levels, such as “low/fairly low/medium/fairly high/high/very high” or “non-existent/chaotic/repeatable/defined/managed/continuously improving” to give us an overall enterprise grade. Fuzzy approaches can also be applicable during this process. Thus, the developed model provides an open structure for the application of a variety of grading

schemes. Applying the measurement instrument systematically to multiple enterprises will eventually lead to the determination of valid thresholds and improved grading schemes. Determination of current positioning with respect to the maturity levels is a critical feedback to managers, since it shows the future direction along the roadmap and the generic path for achieving ultimate collaboration. It also reveals managerial development opportunities for higher levels of collaboration;

2. **For Obtaining a Collaboration Maturity Map for a Number of Enterprises:** If a similar survey-based approach is applied across enterprises, positioning of multiple enterprises with respect to the suggested maturity levels will also be possible. This will lead to a maturity map and a multi-enterprise view, showing clustering patterns and the general positioning of the multiple enterprises around the defined maturity levels. Such a picture will reveal the average maturity behaviour across multiple enterprises. Significant gaps in terms of collaboration maturity levels will be identified, allowing comparison and benchmarking across a number of enterprises. Thus, these stage definitions can be a sound base for benchmarking purposes. Within-network, within-sector, cross-sector, within-country and cross-country comparisons are possible to achieve collaboration maturity. From collaboration perspective, this is a vital network-level feedback, since:
 - a. Partners in need of radical improvement in specific processes can be determined;
 - b. Partners causing hindrance for the overall network collaboration can be identified;
 - c. Main processes in which enterprises fail to collaborate can be determined.

This feedback will enable joint managerial action decisions for the overall well-being of the

network, create an awareness of collaboration, and foster continuous improvement across the network.

L

FUTURE RESEARCH DIRECTIONS

The proposed conceptual model supports further SC research in two aspects:

1. Clearly defined and standardized stage definitions of the model, and mapping of each stage with the processes will establish a common understanding for collaboration maturity among supply chain researchers,
2. In its conceptual form, the model provides an open, flexible structure and a sound base for a number of future research items.

A multitude of survey-based field research can be designed based on the model. Questionnaire-based research studies can be designed at individual enterprise level to determine the current collaboration maturity. The model is generic and it is open for the development of different grading scales and survey instruments. Sector-based customizations and within-sector standardization can be made during the field studies for these measurement scales and survey instruments. Within-network, within-sector, cross-sector, within-country and cross-country comparative studies can also be designed to determine the maturity levels based on this model. Hence, model is valuable to SC researchers for their future studies.

As the field research accumulates along this direction, simplifications or refinements may be suggested for the stage definitions in the long run. Development and standardization of better quantitative measurement instruments, industry-specific customizations for both the survey instruments and maturity level transition thresholds will also follow. Thus, the model can evolve into a practical managerial maturity level assessment and a benchmarking tool along with the accumulation of field research. This assessment will support managers in determining the current maturity

levels and deciding within-enterprise, within-industry and cross-industry managerial actions to improve the SC collaboration.

The model can also be used as a base for the future development of collaboration and trust-related metrics. This study has also shown that future research is still justified in the SC domain regarding the following issues:

- Efforts for clarification, standardization and simplification of ever-increasing terminology;
- Development of causal dependency frameworks among various SC constructs; and
- Empirical studies to investigate the relationships among various constructs.

CONCLUSION

This paper first highlighted the lack of consensus and interchangeable use of the collaboration-related terminologies, and a clarification is provided by means of a dependence and evolutionary sequence diagram. Afterwards, the importance of being smart, innovative and socially responsible in collaborative supply chain relationships is comprehensively discussed in today's Industry 4.0 age. Then, a conceptual maturity model is developed for collaboration. The proposed model is a contribution to SC research by establishing a standardized, conceptual base, and offering a systematic, process-oriented big picture for multi-partner SC maturity.

The model is differentiated from the others by:

1. Providing full process coverage;
2. Extending CPFR model;
3. Defining clear maturity stages for advanced, strategic types of collaboration (like collaborative performance and risk management and collaborative systems assurance and development); and
4. Treating relatively recent terminology like "virtual networks" and "coalescence".

The model is also unique in embedding the recent concepts of smartness, innovation and CSR into a maturity model in relation to multi-partner collaboration.

It is expected that collaborating with Industry 4.0 applications, SCs will become integrated web of networks and increasingly aligned by gaining even more strategic character. In this regard, SC collaboration maturity has to be regarded as a continuously evolving issue with broadening collaboration scopes, and as a transformation from operational to strategic orientation. Within this broadened scope, enterprises have to demonstrate their ability to collaborate in larger scopes and in multiple modes, including joint innovation creation and joint CSR programs to create smart solutions.

KEY TERMS AND DEFINITIONS

Collaboration: Ability of two or more partners to engage in joint activities at strategic, tactical and operational levels to plan and execute SC operations towards a win-win agreement with greater success than when acting in isolation.

Collaborative Innovation: Process of managing the interaction and collaboration of multiple partners to deliver new solutions within a business ecosystem.

Corporate Social Responsibility (CSR): Continuing commitment by business to contribute to economic development while improving the quality of life of the workforce and their families as well as of the community and society at large.

Enterprise Resources Planning (ERP) System: Integrated management information system towards planning, execution and control of all enterprise resources, including money and human resources.

External Integrity: The degree to which a firm can structure its organisational practices, procedures and behaviours into manageable processes across SC partners.

Internal Integrity: The degree to which a firm can structure its organisational practices, procedures and behaviours into manageable processes within the enterprise.

Maturity Model: Staged model describing different evolutionary levels towards improvement and better capabilities.

Smart Supply Chain: Instrumented, interconnected and intelligent SCs with unprecedented levels of integrity and collaboration across multiple SC partners to generate flawless information flow and decision making.

Supply: Chain (SC): Complex networked system of organizations, people, technology, activities, information and resources for moving a product or service from suppliers to customers. Includes channel partners, which can be suppliers, intermediaries, third-party service providers and customers, engaging in planning and management of all activities involved in sourcing, procurement, conversion, and all logistics management activities.

Visibility: Ability to trace all resources (including all physical items, data, information and knowledge) across entire processes and partners to provide a coherent view with a single version of truth across the network.

Concept and Practices of Cyber Supply Chain in Manufacturing Context

Anisha Banu Dawood Gani

Universiti Sains Malaysia, Malaysia

Yudi Fernando

Universiti Malaysia Pahang, Malaysia

INTRODUCTION

In an effort to improve business agility and responsiveness to changing market requirements, many manufacturing companies are decentralizing non-value adding activities by outsourcing. The anticipated benefits of outsourcing are to improve profitability and operating efficiency (Gonzalez, Gasco & Llopis, 2005), reduce capital investment (Lynch 2004), improve business focus (Baldwin, Irani & Love, 2001, Weerakkody, Currie and Ekanayake, 2003), enhance flexibility (Jennings 2002; Lynch 2004), and to gain a competitive advantage (Clott, 2004). This widely adopted business model only solves manufacturer's perennial priorities around cost, growth, risk sharing, and supply chain efficiency. However, achieving the appropriate level of supplier visibility is key, along with investment into greater technology enablement to have an agile and transparent supply chain.

KPMG International's Global Manufacturing Outlook (GMO) Report (2015) shows that while manufacturers are concerned about supplier performance and capacity, the visibility into supplier organizations remains surprisingly low. According to the report, only 14% of respondents (out of 386) claim to have complete supplier visibility into Tier 1 (manufacturers' direct suppliers), Tier 2 (Tier 1 supplier's supplier) and beyond. One of the primary condition for a supply chain to be effective is by integrating the members of the network to ensure an undisrupted information flow. Add transparency to the equation and it in

its entirety becomes a requirement that is achievable by digitally integrating the supply chain, or in the course of this chapter, otherwise termed as the cyber supply chain (CSC).

The advancements in technology has been pivotal in transforming the physical supply chain into an integrated CSC. CSC provides tremendous advances in efficiency and effectiveness. (Linton, Boyson, & Aje, 2014). The benefits of digital integration and collaborations are realized through low cost but rapid transmission of information's which facilitates joint planning and reaction to events, in real-time, by all stakeholders. When integrated for manufacturing, data and information technologies bring intelligence and insight that enables fact backed-up decisions.

This chapter is intended to address this deficiency by comprehensively examining the concept and practices of CSC in a manufacturing context. It is also aimed to provide awareness into the nature of CSC risks and recommend best practices in implementing CSC. Due to the limited literatures pertaining to CSC specifically, this chapter has applied general supply chain management literatures to CSC context while duly differentiating the uniqueness, where applicable.

BACKGROUND

Manufacturing is one of the leading industries of the global economy and is projected to undergo a major transformation driven by power of digita-

lization. Manufacturing industry's share of GDP has remained stable over the last 40 years. According to United Nations Industrial Development Organization (UNIDO), the total contribution of the entire manufacturing sector to GDP, measured as manufacturing value added (MVA), reached an all-time high of \$9,228 billion in 2014. The MVA of developing and emerging industrial economies (DE IEs) for the same year increased 2.4 times from 2000, while their GDP doubled (UNIDO, 2015). Inarguably, manufacturing remains a key driving force of overall economic growth globally.

UNIDO Director General, Mr. Li Yong recognized that the technological change shall become one of the main drivers of long-term growth for the industry:

"In the coming decades, radical innovations such as the mobile internet, the Internet of Things and cloud computing are likely to revolutionize production processes and enhance living standards, particularly in developing countries", he envisioned.

These rising trends are promising evidence that the digitalization of manufacturing industry will dramatically transform the way companies operate in many areas – from Research & Development (R&D) efficiency and faster product launches to supply chain improvements, better operations services and more efficient processes. Oliver Wyman, one of the leading management consultancies in the world, predicts that the global annual margin impact of digital industry across discrete manufacturing in 2030 could be an estimated US\$1.4 trillion (Oliver Wyman, 2016).

As these trends play out in a growing number of manufacturing sectors, the incumbents should concentrate on product innovations and core competencies. Non-core competency activities should be outsourced to suppliers who have the specialization and technological advantage to offer scalability. Therefore, the need for integration among supply chain partners becomes eminent

for a seamless and dynamic collaboration. Consequently, CSC network too can be seen growing in tandem to the manufacturing sectors growth. Thus, it is not far-fetched to conclude that, organization that has a strong and secure CSC are likely to develop a competitive advantage among industry players.

Many researchers have published isolated literatures on the benefits of integrated supply chain (Richey, Roath, Whipple & Fawcett, 2010; Ajmera & Cook 2009; Gimenez & Ventura, 2005; Sabath & Whipple, 2004) its security risks (Boyson, 2014; Elzarka, 2013; Ma, Chen, Meng, & Yi, 2014; Micheli, Mogre, & Perego, 2014; Tummala & Schoenherr, 2011) and integration challenges (Awad & Nassar, 2010; Carter, Monczka, Robert, & Ragatz, Gary, 2009; Pagell, 2004). However, there is no evidence on the concept of CSC and its practices being covered holistically nor has it been attributed specifically to a manufacturing industry. Thus, this paper will answer research question "what is cyber supply chain?" and "how does cybercrime affect supply chain?"

LITERATURE REVIEW

There is a lack of clear definitions and understanding of supply chain management (SCM) in general (New, 1997; Lummus, Krumwilde & Vokurka, 2001; Mentzer et al., 2001; Kauffman, 2002). This problem remains despite a considerable growth in the number of published articles dealing with the topic since the mid-1980s (Stock and Boyer, 2009) due to the unavailability of a good SCM definition (Kathawala & Abdou, 2003). Furthermore, there is no widely accepted definition of related topics such as supply chain integration (SCI) and supply chain collaboration. (Näslund & Hulthen, 2012). However, Mentzer et al. (2001) proposed a broad definition that covers issues related to SCM which can be used to explain any specific discipline such as SCI and CSC. The definition suggested that SCM can be defined as the systemic, strategic

coordination of the traditional business functions and the tactics across these business functions within a particular company and across businesses within the supply chain, for the purposes of improving the long-term performance of the individual companies and the supply chain as a whole. In lieu of this, this chapter introduces the term ‘cyber supply chain’ in defining a digitally integrated and transparent supply chain.

The term ‘cyber supply chain’ is non-existent in literatures on its own to be formally understood as integrated supply chain. Boyson et al. (2009) used the term CSC to represent ‘the entire set of key actors involved with or using cyber infrastructure’. Often many authors conjoin CSC with ‘security’ or ‘risk management’ instead. In fact, the introduction of CSC in this chapter is made by borrowing the term from ‘Cyber Supply Chain Risk Management’ (CSCRM). CSCRM is a new integrative discipline combining elements of cyber security (Boyson, 2014).

Scholars have often used terms like Supply Chain Integration (SCI), Supply Chain Management (SCM), e-Supply Chain Management (e-SCM), Supply Chain Management Integration (SCMI) and other related terms to define an integrated supply chain. However, since the prefix ‘cyber’ describes a control mechanism for information processing in an organization, it is befitting that the very definition of cyber supply chain management implies a governed diversity of hardware and software and system integration activities (Boyson, 2014).

In the context of this chapter, the term CSC is defined as ‘an end-to-end integration of critical supply chain processes between channel partners over secured and intricate digital network with controlled level of transparency’. There are four underlying elements that encompasses this CSC definition: digital network, process integration, security and transparency, which the authors believe to be the backbone of a successful supply chain integration. Thus, CSC is a combination of technology and supply chain management, which

can be further explained by understanding the stages and types of integration.

STAGES AND TYPES OF INTEGRATION

Stages of Integration

Boyson et al. (2009) identified four stages in supply chain integration approach:

Stage 1: Integration activities occur in isolation within own function/department

Stage 2: Internal integration among independent supply chain functions

Stage 3: Integration with external stakeholders, where technology and processes are extended to key customers and suppliers

Stage 4: Cross-enterprise collaboration and optimization with external stakeholders in joint decision making, with real time performance improvement

The CSC approach for the industry incumbent should (ideally) be a Stage 4 where the need to integrate goes beyond integrating to ensure seamless delivery, into having information flow visibility and transparency in a regulated and controlled manner. That is, proprietary information and classified design details must be vigilantly secured from open access yet the customer’s needs and adequate visibility into material demands must be made known so that it drives the requirement and subsequently the fulfilment as desired.

A relatively small sized company, however, may not necessarily undertake a major leap to integrate. Rather it is strategically viable to adopt Stage 1 or Stage 2 approach, depending on their financial capabilities, as these integration software and process are costly, time consuming and resource dependent. Therefore, for a new entrants or Small and Medium Enterprises’ (SME), the initial stages would be a safer starting point.

Types of Integration

In CSC, upstream (supplier) and downstream (customer) integration has emerged as an important element of manufacturing strategy. As discussed, global competition too, demands for the need for an integration among suppliers, internal processes, and customer to facilitate information flow of inbound and outbound flow of information and goods or services. (Won, Kwon, Severance, Lee, & Severance, 2013). Accordingly, Won et.al (2013) proposed three critical types of integrations: with supplier, within the organization and with customer.

Customer Integration

- Concerns with planning, implementing, and evaluating successful relationships between providers (supplier) and recipients (customer) either upstream or downstream of supply chain.
- Is a medium where customers can interact virtually using a secure, uninterrupted systems and be given option to obtain information or place orders ability to real time delivery progress status.
- Must consist of a customer relationships management (CRM) focus on both internal and external customers.

Supplier Integration

- Deals with strategic linkages with suppliers. For example, involving suppliers as early in the product's lifecycle phase in order to ensure advance sourcing and supply of required components to build product.
- Concerns developing a rapid response order processing system that assures reliable delivery and exchanging real time information.

Internal Integration

- Revolves around easy access to key operational data from the integrated informa-

tion system linking to various departments in an organization, accessing to real time inventory information status, utilizing a computer-based planning system between departments.

CRITICAL SUCCESS FACTORS AND ENABLERS

Kumar, Singh and Shankar (2015) have studied numerous literatures and identified 13 critical success factors for an integrated supply chain implementation, namely: top management commitment, development of effective SCM strategy, devoted resources for supply chain, logistics synchronization, use of modern technologies, information sharing with SC members, forecasting of demand on point of sale (POS), trust development in SC partners, developing just in time (JIT) capabilities in system, development of reliable suppliers, higher flexibility in production system, focus on core strengths and long-term vision for survival and growth.

In addition, this chapter has also reviewed four key enablers to a successful supply chain integration from 2009 CAPS research: i) Communication and E-Systems, ii) Organization Structure and People, iii) Metrics and iv) Trust. However, recognizing a need to have a current and redefined enablers, this chapter present six critical success factors for CSC integration by blending previous research with current literatures and business needs:

1. Integration and Information Technology

A secured technology to collect, store and disseminate real time data and information. Equally important are the process and procedures that supplements and encourages use of that data for decision making. Real-time information exchange with suppliers and with customers will create an opportunity where optimization can take place. The keyword here is a secured network that ensures the integrity of the data transmitted across and within supply chains.

2. Cooperation to Collaboration

Willingness to collaborate among supply chain partners both internally and externally are achievable by building trust. Utilization of mutually beneficial contracts or agreement would foster a trustworthy relationship among stakeholders. Manufacturers must involve and consider their suppliers and key stakeholder's ability and limitations in implementing the integration vision and in subsequent decision makings. Early involvement by key players promotes project ownership by those supplier (Nito, 2005)

3. Organization- People, Process, Policies and Culture (3P1C)

Simpson (2010) and Goertzel (2010) have both identified that people, process and technology constitutes the IT enabled supply chain. Boyson (2009) added policy developers as one of the key actors in cyber infrastructure. Adding a collaborative culture of exchanging information openly to reduce uncertainty (Christopher & Lee, 2004), this chapter introduces a 3P1C acronym to represent organizational readiness and receptiveness to adopt CSC as one of its implementation success factors.

4. Customer-Centric Metrics and Incentives

Structured incentives for drivers that facilitate management of shared risk should be developed across the supply chain. Rewards for cost savings and development of ideas that leads to improved products and/or higher cost savings should be offered based on proven and traceable metrics. Incentive-based payment is important (Clegg, Pitsis, Rura-Polley & Marosszeky 2002; Bayliss, Cheung, Suen, & Wong, 2004; Crespín-Mazet & Ghauri, 2007) since it distributes benefits evenly and signals that collaboration is legitimate and desired (Kadefors, 2004)

5. Access Authentication and Authorization

Controlled authorization on who is eligible to access classified and confidential data, and records about who has accessed the data, needs to be managed. This management capability is essential for secure operations and for robust detection and mitigation in the event of a security attack.

6. Transparency

Frameworks to mitigate supply chain risk must promote transparency by all parties. Vendors will need to provide an appropriate degree of transparency into their business processes, and visibility into the controls they use to ensure their product and service development and operations are secure.

CYBER SUPPLY CHAIN BENEFITS

The benefits of an integrated, secure and efficient cyber supply chain to nations and manufacturers are manifold. They ultimately lead to gaining competitive advantage, solving supply and demand related problems, improving supply chain efficiency, lowering operational cost, promoting partnerships across the supply chains and ultimately fulfilling and satisfying the needs of customers. National Institute of Standards and Technology (NIST) under the purview of US Department of Commerce has identified seven possible benefits achievable with CSC:

CYBER SUPPLY CHAIN (CSC) RISKS

In order to answer the second research question, a review on the potential cyber supply chain risks and the measure to secure it need to be looked at. The benefits of information flow in an integrated supply chain are not gained without risks (Smith, Watson, Baker, & Pokorski II, 2007). Access to information also provides an opportunity to cripple the supply chain if misused. The International Multilateral Partnership Against Cyber Threats (IMPACT), an alliance of 152 countries,

has recognized that “cyber threats and attacks are able to strike from virtually anywhere in the world, potentially causing catastrophic social and economic harm” (IMPACT, 2014). The flexibility, scalability, and efficiency of the very technology that enables information sharing between external supply chain partners has also created additional points of access to an organization’s proprietary information, increasing the risk of cybercrime.

Cybercrime is “any crime that is facilitated or committed using a computer, network, or hardware device” (Gordon & Ford, 2006). Common types of cybercrime include denial of services, web hacking and defacement, malware, spam and phishing (Wolden, Valverde, & Talla, 2015), online scams and fraud, (information) and identity theft, attacks on computer systems and illegal or prohibited online content (ACORN, 2016). Any breakdown or security breach in the information system at any point of integration would possibly be detrimental for the organizations reputation.

Manufacturers adopting CSC now must take into consideration the many types of threat scenarios when assessing their cybersecurity. In the past, manufacturers had to worry about cyber-attacks as a form of industrial espionage and thefts. Today however, cyber-attacks can include attempts to take control of production networks and infrastructure for blackmail purposes, infecting plants and equipment with malware to attack end customers, indirect attacks on critical infrastructure via controllers, etc. (Oliver Wyman, 2016).

Confluence of trends and technologies is expected to revolutionize manufacturing industry. Industry 4.0 (the digitization of the manufacturing sector) and Internet of Things (increased machine-to-machine communication) are example of technological advance that has probability to give rise to more threats. Therefore, manufacturers must be aware that when a data is shared between two companies, there is always a potential risk, particularly if one side of the connection is less secure or if a third party is handling the data. Moreover, the data interfaces and connections

Table 1. Benefits of cyber supply chain

Benefits	Details
1. Visibility	Real time visibility across the supply chain
2. Data storage	Untampered, electronic chain of custody of data
3. Traceability	Track and trace products movements and status online
4. Integrated value chain performance	analyze and model across the enterprise to address global performance objectives and take advantage of untapped opportunities for optimization
5. Optimization	Enterprise interoperability sets the stage for collecting and analyzing information and data on processes
6. Predictive analysis	Real-time analytics and modeling to form insights from supply chain interactions
7. Reduced Security and Legacy System Risk	secure environment to share critical data replacing out-of-date systems and equipment

between Business-to-Business (B2B) and vendor applications can themselves become points of cyber vulnerability. A successful breach of any one component could endanger the operation and security of other flows and result in system-wide failure. Lee and Whang (2000) consider achieving the critical balance between integration and security to be among the most challenging and relevant contemporary topics. Thus, it is imperative for manufacturing companies to implement protective measures to secure its CSC network without compromising its data integrity and speed to market opportunity.

PROTECTING CSC NETWORK

Cybercrime is ranked as a top ten risk to the global economy (Oliver Wyman, 2016), evidently indicating that the severity of the cyber threats are not to be taken lightly. No business is immune to the attacks, and thus, must invest its time, resource and

money to secure its CSC network. World Economic Forum (WEF) forecasts that delays in adopting cyber security capabilities could result in \$3 trillion loss in economic value by 2020 (KPMG, 2014). Manufacturers' must adopt a mix of measures to combat cyber threats and improve its supply chain resilience, in the areas of technology, organization, governance, and culture, and integrate them into the company's established risk management processes. These can be but not limited to having redundant backup systems, multiple-stage access for credentials, and ongoing threat monitoring to fend off the expanding list of malware attacks.

Some of the methods that manufacturers can use to address cyber threats are by:

1. **Regular Software Patches:** Patch widely used software on regular basis, systematically.
2. **Controlling Access threshold:** Govern and restrict access to sensitive data by monitoring which users have access to data and what they are doing with it.
3. **Periodic Internal Assessment:** Conduct regular audit to check vulnerability, limit internet usages, restrict external storage device and other media recording ports.
4. **Cyber Education:** Educating internal and external stakeholders on importance of cybersecurity.
5. **Security Certification:** Obtain certification from recognized, external auditors to ensure compliance to security standards as a mean to prove credibility.

Manufacturers must note that despite implementing the recommended steps above, it would still be insufficient to protect the organization without their Tier 1 and Tier 2 suppliers being secured as well. This can be achieved by surveying vendors' security practices across a supply chain network and applying security research, developing the IT capabilities needed to better examine and predict potential threats.

SOLUTIONS AND RECOMMENDATION

The significance of making an informed decision concerning supply chain activities cannot be undermined. In order for firms to obtain real time data, they must increase their visibility into their supply chain networks. Thus, firms are strongly recommended to invest in having a CSC to have a 'single version of truth' pertaining their business. The following measures are recommended to mitigate risks associated with CSC:

1. **Perform Risk Assessment:** Identify the types and storage of the data that is valuable to the organization, and establish protection and recovery plan.
2. **Establish Security Plan:** Define how assets would be protected, how threats can be detected and how to respond to security breaches.
3. **Hire Security Detectives:** Setup job role and hire right sets of people who are able to execute the security plan.
4. **Invest in Cybersecurity Solution:** To assist with threat detection and data encryption for a resilient supply chain.

The success factors of these security hygiene's rely on engaging and involving stakeholders to equally adopt the security practices.

DISCUSSION AND FUTURE RESEARCH DIRECTIONS

Today's global supply chains rely upon fast, accurate and secure dissemination of data among supply chain partners. The need for businesses to integrate does not appear to be slowing down with the industrial revolution predicted. However, CSC is often researched from an individual firm or a specific industry's perspective in separation.

Would businesses be more receptive to adopting CSC and cybersecurity solutions if they are guided and provided necessary startup and post-startup support? It would be fascinating to conceptualize firms' receptiveness to CSC and cybercrime by exploring the idea of setting up a national level cyber-resource center that governs cyber ecosystem by providing businesses, government and academia the sources, training and consultancy required to identify, mitigate and protect themselves from being a cybercrime victim. The findings might change the security landscape of a country.

CONCLUSION

Technological advancements are drastically transforming manufacturing industry, which in turn is driving the need for cyber supply chain (CSC). CSC enables manufacturing companies to reap numerous benefits from cost savings, efficiency improvement to ultimately gaining competitive advantage. There are three types of supply chain integration: with customer, supplier and internal and six critical success factors for implementation; i) integration and information technology, ii) cooperation to collaboration, iii) 3PIC (people, process, policies and culture, iv) customer-centric metrics and incentives, v) access authentication and authorization and vi) transparency. However, CSC is not gained without risks, therefore manufacturing companies must undertake several steps to protect their supply chain network, for example, by restricting access to sensitive information, performing regular software patches, conducting periodic audit, creating awareness among its stakeholders and obtaining security certification to imply compliance. Manufacturing companies must have top down management's support to turn cybersecurity as a culture and to allocate funds to invest in cybersecurity solutions. None of these measures would be fully successful without stakeholders participating in adopting the security hygiene practices.

KEY TERMS AND DEFINITIONS

Cyber Supply Chain: An end to end integration of supply chain over secured and intricate digital network.

Cybercrime: Any crime that is facilitated or committed using a computer, network, or hardware device.

Cybersecurity: Mechanism to fend off cyber crime.

Digitalization: Use of digital technologies to change a business model.

Risk Management: Procedure to avoid and minimize risks.

Security: Free from danger and threats.

Supply Chain Integration: Coordination within a supply chain using integrated system.

The Concept of Modularity in the Context of IS Project Outsourcing

INTRODUCTION

Due to the globalization of the world economy and advancement in information and communication (ICT) technologies, information systems (IS) outsourcing became a very common practice in developed and in emerging economies. Over 94% of 'Fortune 500' companies are outsourcing at least one major business function (Modarress, Ansari, & Thies, 2014). Despite IS outsourcing's popularity, failure rates are high. Premature contract terminations and frequent dissatisfaction with IS outsourcing results are commonly encountered. Many IS outsourcing failures are not even reported publicly due to the fear of negative consequences from the market and the stakeholders. Empirical research has attempted to quantify the high probability of IS outsourcing failures. For instance, a joint study in 2000 by Oxford University's Institute of Information Management and the University of Missouri, which tracked 29 major IS outsourcing projects over eight years, reported that more than 35 percent failed (Gay & Essinger, 2000). A second study by Martineau and Shumway (2009), which compared data from 2004, 2006 and 2009, concluded that by 2009, the percentage of failed IS outsourcing projects (i.e., cancelled prior to completion or delivered and never used), being

44%, had decreased but was still (too) high. In the same study, the percentage of challenged IS projects (late, over budget, and/or with less than the required features and functions) also decreased by 2009 but still amounted to 32% in 2009. It is implied that the success rate in 2009, being 24%, did increase over time but was still low (Ciric & Rakovic, 2010). In this paper the authors are illustrating an alternative and new approach, based on the concept of modularity, which may supplement other approaches in order to significantly reduce the high failure rate in outsourcing. The newness of the proposed perspective is clear from Fixson, Ro, and Liker (2005, p.167) who state,

in the past, modularity and outsourcing were investigated predominantly in separate research communities but more recently, however, a new research stream has emerged that links these two topics together.

Modularity is defined as a property of a complex system, whereby the system is decomposed into several subsystems (i.e., modules). Modules are the decomposed and nearly independent parts of a larger system; the modules are less complex than the larger system. The decomposition of a larger system into modules allows breaking apart

or splitting up the complexities into smaller pieces (modules). The modules are still (mutually) compatible as, together, they work as a whole towards a common goal. The modules' compatibility logically follows from the adoption of specific 'design rules' (i.e., a chosen design option; see later) using an interface as connector (Langlois, 2002). The interface should be 'well-defined' (i.e., leaving no room for ambiguities) as it describes the input a module requires to perform its (functional) task, and the output it provides to its external environment (which includes the other modules embedded in the system). The amount of dependent 'design parameters' between different modules determines their coupling. Good modular design requires low coupling as low coupling enables design parameters of modules to remain stable, that is any change in the design parameter of one module has no or limited impact on the design parameters of other modules. A good modular design therefore exhibits the following two properties: (a) if the design of one module needs to be changed, the change will have no or only a limited impact on the design of other modules, and (b) the function of one module can be studied more or less in isolation from the functionality of the rest of the system. In order for necessary intermodular dependencies to work adequately, all intermodular dependencies should be clearly defined / made explicit *ex ante*, that is no hidden dependencies are allowed for (Mannaert & Verelst, 2009). If all intermodular dependencies in a system are clearly defined, a set of prescriptive rules is obtained, which all modules of the system need to adhere to. This set of rules is referred as the 'modular architecture'.

BACKGROUND

A pertinent question deals with how IS outsourcing failure may be avoided. So far, literature includes many suggestions ('remedies') offered by both scholars and practitioners. Peterson and Carco (1998) suggested to streamline operations and 'fix the problem' before outsourcing an IS.

Various remedies were introduced; the interested reader is referred to:

1. Lambert, Emmelhainz, and Gardner (1999) who introduced their '*Partnership Model*';
2. Greaver (1999) who formulated '*seven steps to successful outsourcing*'; and
3. Rottman (2008) who elaborate on the importance of 'knowledge transfer'; and
4. Harris, Herron and Iwanicki (2008) who stressed the importance of a high quality 'service level agreement' (SLA).

Despite the introduction of such remedies, the empirical research referred to above continues to attest to the high failure rate of IS outsourcing projects. It seems these remedies turned out to be partially successful at best. Partial successfulness may be due to the fact that most of those remedies focus on treating the symptoms (i.e., the consequences) rather than the causes of ineffective IS outsourcing. As a consequence, it is plausible that some important outsourcing risks were not identified *ex ante*. The desire to be better equipped to identify outsourcing risks *ex ante* has fueled the study presented in this paper. As a matter of fact, this paper presents an alternative, new perspective on how to avoid IS project outsourcing failures. The new perspective goes beyond the higher-mentioned remedies, and explores the concept of modularity in relation to IS outsourcing projects. Such a new perspective, which originates from the system sciences, may add value to outsourcing risk analyses. The added value comes from new or deeper insights which are instrumental in defining an exhaustive list of required mitigating actions, which is key for a successful completion of IS outsourcing projects. To illustrate the new perspective, a reanalysis of a failed (actual) outsourcing case is discussed. The paper shows in detail how poorly designed modular structures at the project level could have been identified *ex ante*. This approach is similar to the application of modularity to other context, such as requirements engineering (Verelst et al., 2013).

CASE INTRODUCTION

The selected case deals with a vendor organization, referred to as 'Aries', and a customer organization, referred to as 'Taurus'. Aries was regarded as a competent and reputed service provider and Taurus was a public sector university. The IS outsourcing project was rather small and simple. Taurus needed a web-based portal for academics' records management (e.g., new applicants' data, students' data, exams' data etc.). Taurus formed a team (hereafter 'focal team') of specialized professionals who had to deal with all aspects of the IS project and communicated to the Aries' team. After encountering many problems and extending project duration for 12 months, the project was categorized as a failure by the both parties. Taurus was unsatisfied with the delivered solution and did not use the new web-based portal. Aries was asking for more time and money to complete the IS project according to the demands of Taurus.

METHODOLOGY

This study relied on

1. An in-depth literature review and
2. A re-analysis of the IS outsourcing project (the case) using inference logic.

The in-depth literature review consisted of a systematic, step-by-step approach to collect, synthesize, analyse, and highlight the relevance of the modularity concept in the context of IS outsourcing. The literature review started with a systematic procedure (i.e., framing questions, identifying relevant work, assessing the quality, summarizing the evidence, and finally interpreting the findings) to identify and collect relevant papers which may be instrumental in achieving the study objectives (Webster & Watson, 2002). Next, data (i.e., paper texts) were collected and

analyzed thoroughly. For a literature review to be adequate (e.g., 'effective'; see Bandara, Miskon, & Fiel, 2011) 'key concepts' to capture and report on are to be formulated a priori (and revised during the literature review). The a priori list of key concepts included: '*modular systems*', '*modularity*', '*coupling*', '*dependencies*', '*IS outsourcing*', and some other, related concepts. Through an in-depth analysis of textual data, the nature of the relationship between the concept of modularity (e.g., dependencies, and coupling) in the context of IS outsourcing has been explored. Key findings from the literature review were supplemented with findings obtained from reanalyzing the case (introduced above). Benbasat, Goldstein, and Mead (1987) justified the use of 'case study analyses as it facilitates capturing practitioners' knowledge and developing theories from such knowledge. For this case analysis, a qualitative research approach was considered most suitable as this case study deals with a contemporary phenomenon (e.g. modularity, IS outsourcing) where the boundaries between the phenomenon and context are not clearly evident (Yin, 2011). The case selection criteria for this paper are the following:

1. Sufficient information should be available to explore the applicability of the concept of modularity;
2. The IS outsourcing project should have been presented and discussed already in the literature in order to explicitly illustrate how the outcome could be different if the concept of modularity were relied on *ex ante*.

The case study research efforts were aimed at better understanding the extent to which practitioners (working on an outsourced IS project) design fine grained modular structures. In addition, the re-analysis of the case may also illustrate how fundamental concepts such as modularity can be applied in practice.

FINDINGS: ANALYZING IS OUTSOURCING FAILURE

Analyzing the case, it has been revealed that some unfortunate decisions had been taken by the vendor and the customer that might have led to the failure of the IS outsourcing project. Concerning the service level agreement (SLA), Nauman and colleagues (2009) stated that “A weak legal environment in the developing countries ... does not allow the development team to challenge the client on the basis of Service Level Agreement” (p. 273). Even though the statement is a valid, it does not facilitate an understanding of why (some) unfortunate decisions were made, or why the problematic consequences occurred. Put differently, such an analysis does not look for the root causes of the observed project failure. In order to investigate these root causes, it is worthwhile to re-analyze the SLA from a modularity perspective. In re-analyzing the case, some deficiencies regarding the SLA were identified. For instance, incongruent with modularity, the SLA contained ‘hidden dependencies’ as referred to in the introduction. Apart from the SLA, other violations against the principles of modularity were found as well. Further on in the text it is illustrated how the implications of these violations of modularity have been identified by Nauman and colleagues (2009) to lead to the IS outsourcing project failure. Consequently, these violations can aid during the identification of the root causes for project failure in IS outsourcing projects. The violations against modularity -- and therefore root causes of failure -- are typically identified *ex post*. However, the formulation of an analysis framework based on the modularity-perspective could aid in detecting these violations *ex ante*. The re-analysis of the case therefore follows three recurring steps. First, to adequately identify modularity aspects in a certain part of the case, a subsection “Identifying the modular structure” is used. Second, this paper describes which requirements modularity prescribes with regard to the identified aspects

under a subsection “modularity requirement”. Third, evidence from the original case description is presented which illustrates how these modularity requirements are violated under a subsection “Assessing the modularity requirements”. Obviously, any violation of modular design principles may, at least partially, contribute to the failure of IS outsourcing project.

1. Analysis #1: Service Level Agreement (SLA) consisting of undefined or hidden dependencies

In the introduction it was stated that modules should interact with one another through the interface. To function adequately, the interaction between modules should be exhaustively and unambiguously documented in the interface. As far as the SLA is concerned, responsibilities of each module, rights of each module, and the relationships between modules are to be described in detail. In the context of IS outsourcing project, the SLA essentially provides an interface between the vendor (team Aries) and the customer (the focal team of Taurus).

a. Identifying the modular structure

Based on the paragraph just above, team Aries and the focal team of Taurus are conceived as modules and the SLA serves as the interface connecting both teams.

b. Modularity requirement

As explained in the introduction, team Taurus is only allowed to ask team Aries for services which are described in the SLA. Any service asked for which is not described in the SLA constitutes a hidden dependency, which may result in unwanted outcomes, namely coupling and/or CEs. As mentioned earlier, in a good modular design all intermodular dependencies are made explicit, that is no hidden dependencies are allowed for.

The explicitness of intermodular dependencies is now referred to as modularity requirement #1.

c. Assessing the modularity requirements

After many hurdles and delays, the out-sourced IS project completed the ‘testing phase’. As agreed in the SLA, after the testing phase, the Taurus team leader would start to lead the implementation of the IS project. But within three months the Taurus focal team discontinued implementing the project and asked the Aries team to appoint an expert who would supervise the entire implementation process, and to train the end users in using the new IS system. As such services were not part of the SLA, which was agreed upon by the both parties, the Aries team declined to offer such services without getting a financial benefit. In turn, the Taurus team was inflexible and insisted on receiving the services for free. As a result, both teams eventually turned away from the IS project.

The following excerpt shows that the SLA consisted of hidden (i.e., undefined) dependencies:

Head of Department of Computer Science started to lead the team to implement the project. However, the project implementation came to a standstill when the client organization desired deputation of full time experts by the customer organization to supervise the implementation which included training of the end users to use the system and subsequently adopt it. Vendor expressed their inability to depute an expert without charging further expenditure to customer (Nauman et al., 2009, p.271).

Team Taurus asking for unanticipated support from team Aries indicated an undefined intermodular dependency. The SLA specifying the dependencies between team Taurus and Aries is, therefore, said to be poorly defined and contains hidden dependencies. As such, requirement #1 was not met.

2. **Analysis #2:** No Standard Procedures and Definitions

A good analysis of IS system requirements (and thus a well-designed IS system) is critical to successful IS project outsourcing. Adequate analysis of IS system requirements should result in a well-designed IS system. As far as the Taurus organization is concerned, a single IS should serve all the departments of this organization with a standardized operating procedure. The specification of IS system requirements in such a context becomes challenging when different departments currently use different operating procedures for similar tasks.

a. Identifying the modular structure

Different departments of the Taurus organization are conceived as representing different modules. Different departments followed different procedures for the same tasks, and for some particular tasks there were no standard operating procedures. Using modularity terminology, the different departments were using different design options. In this part of the analysis the focus is on the ‘design options’ aspect of the concept of modularity.

b. Modularity requirements

As explained above, a (well-chosen) ‘design option’ (characterizing standardized operating procedures) should become a ‘design rule’. Knowing the design rule(s) chosen by organization Taurus, team Aries is able to conduct, with a high degree of reliability, an IS system’s requirements analysis. When adequately designed, the IS system should be able to serve all the common processes in the different Taurus departments. An unattractive alternative is not to decide on the design rule(s), and design a customized IS for each Taurus department. Obviously, both the cost and complexity of the unattractive alternative is

higher. As far as analysis #2 is concerned, the ex ante requirement for the “design option” aspect of the concept of modularity is as follows: “The Taurus organization should select a design rule from the existing design options or, alternatively, a new design option to serve all the common business processes throughout the departments. All departments should adhere to the design rule(s) selected”. Adherence to design rules is referred to as modularity requirement #2.

c. Assessing the modularity requirements

Team Aries was described as a “very competent and well reputed provider as it was one of the leading independent companies working as a business unit of a large and reputed international company” (Nauman et al., 2009, p. 269). Despite being deemed very competent and reputed, team Aries realized too late (during the testing phase) that for some processes Taurus organization had no standard operating procedures, and for the same business processes, different departments were following different operating procedures (Nauman et al., 2009).

Nauman et al. (2009) also diagnosed Taurus’ organizational processes to be inadequate to embrace automation and needed re-engineering. According to Nauman and colleagues this inadequacy was one of the main reasons why this IS outsourcing project failed (Nauman et al., 2009). Just one example of a faulty data definition is: “the pattern [i.e., the structure] of student registration numbers varied in different departments. Such anomalies caused some requirements changes, even at the later phases, and delayed the implementation” (Nauman et al., 2009, p. 271). Due to different operating procedures adopted by different departments the project was delayed. The above excerpts indicate that Taurus organization failed to select a design rule from a range of alternative design options. As the Taurus organization failed to decide on a design rule it is clear that modularity requirement #2 was not met.

3. **Analysis #3:** As the people changed, the mindset changed and the vision about the project also changed

Change is inevitable within organizations and accommodating change poses a challenge. It was observed that the Taurus team composition changed three times over the course of the project (fig.1). In analysis #3, non-technical root causes of failure are dealt with. The team’s composition can be interpreted and explained in terms of modular structures (Huysmans et al., 2014). As Terlouw (2011, p. viii) states, “modules can comprise humans and/or software systems”. In addition, Dietz (2006) proposed a method to identify modular actor role structures (Huysmans et al., 2014) and thereby asserts that “an enterprise is constituted by the activities of actor roles, which are elementary chunks of authority and responsibility, fulfilled by subjects” (Dietz, 2006, p. 81). As being said, the Taurus team composition changed; some members were replaced by new members. To minimize the impact of changes within the Taurus team, management appointed a software engineer to lead the Taurus team, and expected him to coordinate with the Aries team, up till the end of the project. Unfortunately, almost at the end of the project, during the IS testing phase, this team leader also left for another job and the head of the department of computer science became the new team leader.

Table 1. Different compositions of the Taurus focal team

Team Composition	
1	The Taurus focal team comprises senior faculty members from different departments; the team leader was one ‘Head of department’ (1 st team leader).
2	Due to some routine and policy decisions some team members were replaced by new team members.
3	A software engineer was appointed as new team leader (2 nd team leader).
4	(During the IS testing phase) the team leader left for another job and was replaced by the ‘Head of the computer science department’ (3 rd team leader).

Each change of Taurus' team composition caused some kind of hindrance to the project. Since the Taurus team was previously considered as a module, the next step of the analysis concentrates on the sub-modular level. This illustrates the usage of modularity as a hierarchical concept.

a. Identifying the modular structure

The module 'Taurus organization', as a first level of modularity, can be further subdivided in two (hierarchically nested) levels of submodules. A first submodular level refers to the Taurus 'focal team', and the second submodular level refers to an individual team member, for instance a member of the Taurus 'focal team'. In analysis #3, the Taurus organization and the Taurus 'focal team' are considered to represent a module and sub-module, respectively. The analysis is at sub-modular level, and the analysis focuses on the 'substitution' operator which is part of the modularity concept (i.e., a modular operator).

b. Modularity requirements

In a well-designed modular IS, applying the modular operator 'substitution' should not impact the existing structure negatively. Terlouw (2011, p. viii) asserts that "the modular operators are the actions that may change existing structures in a well-defined way in order to enhance the efficiency of the system". Huysmans, et. al, (2014, p. 4418) suggest that "substituting an older version of module with the newer version should ameliorate the overall performance of the system". The substitution modular operator can be applied successfully and relatively easily if all module versions adhere to the same interface and no undocumented intermodular dependencies are present. If the interface is changed, or the dependencies of the modules are not made explicit, the application of the substitution modular operator is not without risk; one risks that applying the substitution operator disrupts the working of the system, and may trigger ripple effects.

When considering a team as a modular structure, the interface includes the boundary of authority. Consequently, these boundaries should be made explicit and should not change when the module is substituted. Restricting or freezing the boundaries of each module will facilitate to identify any hidden dependencies between the modules and also safeguard the integrity of the modular architecture. A modular architecture describes as "a predefined set of prescriptive rules which all modules of the system need to adhere to" (Huysmans, et al., 2014, p. 4418). This definition clearly indicates that once the modular architecture is designed, the modules (members of the focal team) are obliged to adhere to the predefined rules. The modules should remain within their defined boundary and should not overstep it. So, the boundary of the modules of focal team should be defined clearly and the integrity of the modular architecture should remain unchanged. This condition is considered as modularity requirement #3.

c. Assessing the modularity requirements

In this case it has been observed that the composition of the sub-module "*focal team of Taurus*" has changed three times (fig.1). Using modularity terminology, this means that the sub-module has been substituted three times. Initially, the leader of the focal team only acted as a facilitator in order to communicate effectively and efficiently with the vendor 'Aries'. Therefore, the focal team leader has no authority to make any changes to the project conditions which were already agreed upon by all the stakeholders. According to the concept of modularity, modules are supposed to be free of any hidden dependencies and it does not threaten the integrity of the modular architecture.

In reality, this was obviously not the case. Whenever another version of the focal team was put in place, already established agreements between both parties (i.e. requirements specification was developed and agreed upon by the customer and the vendor) tended to change. Substituting sub-module "*focal team of Taurus*" with newer

versions was negatively affecting the efficiency of the project which can be observed by the following excerpts: “Changes at the organizational level ... led to some new requirements emerging from nowhere and caused frequent changes in the old requirements...The new members of the focal team were not clear about the scope and objectives of the project... Due to this kind of divisive environment, a huge time was lost in the advancement of the project” (Nauman et al., 2009, p. 270). The above excerpts illustrate that applying the modular operator “substitution” resulted in chaos and the modules did not remain within their defined (allocated) boundary. This led to the loss of integrity of the modular architecture. Therefore, in this situation and in the context of this case, it can be concluded that modularity requirement #3 was not met.

FUTURE RESEARCH DIRECTIONS

This is the 2nd IS outsourcing case analysed by the authors using the lens of modularity. These two findings may not be enough to generalize but

in the future, additional case analyses might lead to theory building and a set of hypotheses can be derived from it. In future studies, the newly emerged hypotheses can be tested quantitatively.

CONCLUSION, CONTRIBUTIONS, AND LIMITATIONS

IS project outsourcing became an important business strategy for many organizations. Unfortunately, despite academics’ and practitioners’ efforts made, failure rates of such projects remain far too high. This paper goes beyond the remedies proposed by academics and practitioners, which were partially effective at best, and offered a new perspective based on the concept of modularity. To the best of the authors knowledge, the concept of modularity has never been explored in the context of IS project outsourcing failure. Based on the information from a documented case study (i.e., an outsourced IS project that failed) and reliance on this new perspective this paper shows that specific factors that have contributed to IS project failure could have been identified ex ante.

Table 2. Summary of the findings

	Analyses 1	Analyses 2	Analyses 3
Modular Structure	The Aries team (vendor) and the focal team of Taurus (customer) are conceived as modules.	Different departments of the Taurus organization are conceived as modules.	The Taurus organization is conceived as a module and the Taurus focal team is conceived as submodule. In analogy, every member of the Taurus focal team is conceived as (sub) submodule. This analysis is at the sub-module level.
Modularity Aspects	Dependencies (hidden)	Design options	Modular operator “substitution”
Modularity Requirements (ex ante)	All intermodular dependencies should be made explicit, no hidden dependencies are allowed.	The Taurus organization should set a design rule to serve all the common business processes throughout the departments. All departments should adhere to the design rules.	The substitution operator can be applied successfully and relatively easily if the intermodular dependencies are explicit (i.e. no hidden dependencies are allowed)
Violations	All intermodular dependencies between two modules (Aries and the focal team of Taurus) were not identified ex ante. The SLA was poorly defined and consisted of undefined or hidden dependencies.	The Taurus organization had no standard operating procedures; different departments employed different operating procedures.	Substituting the older version of submodule Taurus focal team with a newer version negatively impacted the efficiency of the IS project. Applying the modular operator “substitution” was very difficult and most likely unsuccessful.

Identified factors related to a poor formulation of system requirements and violations of design principles underlying the modularity concept. This study is of practical use as insights in these factors that contributed to IS project failure are relevant to practitioners (e.g., project managers, software developers). The study is also relevant from a scientific point of view as the concept of modularity (in relation to IS project outsourcing) has been discussed in the scientific literature (see, for instance, Fixson, Ro, & Liker, 2005, p.167) but most of those literature are descriptive in nature. The current study adds to this scientific literature by going a step further, more specifically, the current study succeeded in illustrating how outsourcing projects can reap the benefit by applying ex ante the concept of modularity.

ACKNOWLEDGMENT

The authors are indebted to Prof. Dr. Alain De Beuckelaer (Institute for Management Research, Radboud University, Nijmegen, Netherlands) due to his contribution in improving the quality of this paper.

KEY TERMS AND DEFINITIONS

Coupling: Coupling is a measure of the dependencies between modules.

Design Rule: A well-chosen ‘design option’ (characterizing standardized operating procedures) should become a ‘design rule’. Compatibility among modules is ensured by “design rules”. Sometime modules are designed independently but at the end these modules should work as a whole. Standard dimensions and parameters or specifications (i.e., dimensions, tolerances, functionality, dependency etc.) constitute design rules.

Interface: An interface is a common boundary where direct contact between two modules occurs and where these two modules communicate with each other.

Modular Dependency: Dependency is the degree to which a module relies on other modules in order to function.

Modularity: Modularity is defined as a property of a complex system, whereby the system is decomposed into several subsystems (i.e., modules).

Module: A module is a unit whose internal parts are powerfully connected among themselves and relatively weakly connected to other units.

Developing Global Supply Chain Manager for Business Expansion

Puspita Wulansari

Universiti Malaysia Pahang, Malaysia

INTRODUCTION

Globalization makes market becomes more competitive since nowadays the problem of geographical boundaries which hinders marketing of products and services can be overcome more easily. With the help of technological advancements, such as the internet and logistics, products and services can be marketed and consumed in any part of the world rather easily. Customers can freely choose the products and services based on their preferences on price, quality, or mode of acquisition (Morgan, 2003).

To win the competition in the global market, it is not enough for a company to operate on local level alone. Kiessling (2013) and Flint (2004) explain that with the global market, the products and services provided by MNCs can reach closer to customer value from all parts of the world. Compared to selling the product locally, global market shares are indeed much bigger. It has to operate globally, sell their products and services internationally. As an example, three brands which are produced by local companies but are already known as an international product, Nestle Coffee, Levi's jeans, and Carrefour, have to compete with superstores such as Wal-Mart (Hammond and Grosse, 2003). Local companies have to think globally and slowly transform themselves to become Multinational Corporates (MNCs) (Hammond and Grosse, 2003; De Chiara and Spane, 2011). Multinational companies operate in multiple countries, and they move products,

services, cultural styles, and economic power from one country to the others (Hammond and Grosse, 2003). For example, a German multinational engineering and electronics company, Robert Bosch GmbH, has established more than 350 subsidiaries across over 60 countries. Unilever, a London-based multinational consumer goods company, has created subsidiaries in at least 90 countries (Nguyen et al., 2015).

One of many ways for MNCs to be competitive is that the firm has to produce products and services which meet customers' preferences, which are: having high quality with affordable price (Griffith, 2006). MNCs which operate in multiple countries can get 4 location advantages by utilizing different characteristic from each geography, which are: resources, efficiency, market, and strategic asset (Dunning, 1998; De Chiara and Spane, 2011). MNCs have to think and find another alternative of raw materials with affordable cost from other countries. They also have to consider ways to shorten their time cycle to deliver products to customers and to minimize logistics cost. In addition, as an effort in terms of resources and efficiency, they have to find operating locations which have lower labor and resource cost (De Chiara and Spane, 2011; Christopher et al., 2006).

The needs to think globally and act locally can be materialized by utilizing supporting concept of global supply management. The global supply chain in MNCs will force companies to pay attention to supply chain matrix to achieve cost

reduction, better time utilization in production line, faster shipment, cheaper labors and satisfaction (Flint, 2004; Mollenkopf et al., 2010; Manuj and Mentzer, 2008).

The dynamics in business environment and buildup of the global market force the parties in supply chain to be equipped with different skills and competencies to facilitate them to manage the larger scope of global supply chain successfully (Hohenstein et al., 2014). A global supply chain manager's role is to handle the workflow of the materials and products across domestic and global markets. Capabilities and competencies to manage resources globally play a key role to enhance supply chain management (Keller & Ozment, 2009).

Earlier studies show that the effectiveness of supply chain management operations are disrupted by unclear goal setting implementation from an organization, and this can be improved through better human resources (Gowen & Tallon, 2003). According to Ellinger and Ellinger (2014); and Kiesling et al. (2004), supply chain management role has been changed dramatically in terms of required skill set, knowledge, and capabilities for them to be able to connect and run a global operation.

The importance of a global manager's role to support global supply chain management in MNCs is very critical. Earlier researches in understanding the importance of human resources in supply chain management have been conducted, but a specific research in global supply chain management has not yet been conducted—to be specific, on *building* global supply chain management in MNCs—only a few scholars conduct this before. Within this chapter, we will deepen the analysis on the competency required by a global supply chain manager in relation to his role to support business expansion globally, based on the previous study which has been published in the academic journals.

This chapter is structured as follows. The next section presents a short background on the growing importance of global supply chain managers. In the following section, in the main focus of this

chapter, previous researches about global supply chain management and its intersections with human resources management will be discussed. After the problem has been identified, the next chapter is designed to digest further the solution and recommendation, followed by future research direction, and to be closed with a conclusion.

BACKGROUND

In the beginning, supply chain management was only established in local companies. With globalization coming along the way, companies need to develop strategies related to supply chain management. Global supply chain management will allow company to utilize benefiting factors of varied location globally, for examples: level product and process technology expertise, labor force capabilities, input factors cost, local tax rates, and the capabilities offshore vendors (Cohen and Malik, 1997).

Global supply chain management will deal with varied interests from business management and supplier globally rather than locally, thus it requires manpower which can supervise effectively all of the activities of global supply chain and can collaborate internationally (Harvey et al., 2013). Involvement of human resources on the success implementation of global supply chain management is an interesting topic which has not been studied widely by researchers. It is well known that human resources can boost company's performance through strategic management of the knowledge, skill and HR capabilities. Human resources managements in general are series of activities such as recruitment, selection, training, performance management, compensation, labor relations to manage staff of the organization (Ivancevich, 2003). With the global world development, MNCs are required to manage human resources management in much more sophisticated ways. Compared to local companies, they have to ensure the recruited staff is the most talented staff

with the right knowledge, skill set and motivation to be positioned across company branch which may be located far away from where they belong to (Hohenstein et al., 2013).

Having a global manager who can establish good relations is considered to be one of the most important benefits in this competitive global market. As a result, companies do not consider customer and supply chain as a result from business action but rather as an asset which is needed to be developed and optimized (Harvey et al., 2013). Harvey and Richey (2001) explains that the perspective based on the competencies explicitly can overcome the dynamics of the global environment by understanding since the beginning the competencies owned by a global supply chain management during the recruitment process and followed by development after onboard. Competencies development is expected to enable the global supply chain management to define the strategic objective. By identifying the importance of global leadership competencies, corporates might be able to shorten the long period of time for developing global leaders. Thus, identifying global leadership competency model must be an urgent priority for the company so that they can adapt and survive in a changing global environment (Kim and McLean, 2015).

For further understanding, below are definitions for key processes on this chapter, such as supply chain management, global supply chain management, and human resource management, as they are defined by the experts.

Supply Chain Management

According to Mentzer et al. (2001), supply chain management is defined “as a systemic, strategic coordination of the traditional business functions and the tactics across these business functions within a particular company and across businesses within the supply chain, for the purpose of improving the long-term performance of the individual companies and the supply chain as a whole.”

Global Supply Chain Management

Definition of global supply chain management is “a network of facilities, activities, and social relationship that performs a multitude of integrated value-adding function in a global context (Mabert and Venkataramana, 1998 in Harvey and Richey, 2001). Or can be defined beyond the range of functional and relational activities undertaken by the downstream/upstream stakeholders in the supply chain (Harvey and Richey, 2001).

Human Resource Management

According to Ivancevich (2003), human resource management is “the function performed in organizations that facilitates the most effective use of people (employees) to achieve organizational and individual goals.” Meanwhile Dessler (2013) stated that human resource management is “the process of acquiring, training, appraisal, and compensating employees, attending to their labor relations, health and safety, and also fairness concerns.” Human resource management activities consists of numerous activities, which are:

1. Equal employment opportunity (EEO) compliance,
2. job analysis,
3. human resource planning,
4. employee recruitment, selection, motivation, and orientation,
5. performance evaluation and compensation,
6. training and development,
7. labor relations,
8. Safety, health, and wellness (Ivancevich, 2003).

Global Supply Chain Process

With development and expansion made to various country, role of supply chain management and logistic become much more critical factor for companies. MNC need to drive the supply

chain on their international network, where they not only required to manage the distribution of product and service globally, but also to focus on organizational learning by looking through the competitive advantage from the competitor (Kiessling). Therefore, MNC can operate their business as multinational player, where part of the global supply chain process are international manufacturing plants, purchasing and sells on global markets, multinational staffed, executive boards, and multicultural personnel (Hulsmann et al., 2008).

However, implementing the global supply chain is not simple. There are numbers of obstacles need to be faced and solved by companies, such as cultural economical, language and legal differences in various countries. The complexity and coordination involved in management, and geographical distance from one area to another not only costing on transportation cost, but also on inventory cost (Mollenkopt et al., 2010; Meixell and Gargeya, 2005; Kiessling et al., 2004).

In order running the Global Supply Chain Management process, it takes a huge effort. It needs human resource with certain skill set and competencies, by then they can manage to process from downstream to upstream from various countries. In the same time, companies need to have the capabilities to develop global supply chain managers. In order to develop global supply chain managers, it is important to understand the required competency for talents to be able to execute his role successfully in the global market.

Scholar has been conducting the research to understand the role of human resource management and global supply chain management as well as the competencies needed to become a global supply chain manager.

More specifically, Harvey and Richey (2001) mentioned that global supply chain managers need to possess;

1. Input competencies, i.e. capital, labor, and physical assets.

2. Managerial competencies, i.e. social managerial knowledge, informal business networks both internal and external.
3. Transformation-based competencies, management competencies to execute the task, to be in the proper position in the market place, and adaptability in the new organization environment.

They also discussed multiple intelligence for world-wide supply chain managers, which are;

1. Cognitive intelligence;
2. Emotional intelligence;
3. Political intelligence;
4. Cultural/social intelligence;
5. Organizational intelligence;
6. Network intelligence;
7. Innovative intelligence; and
8. Intuitive intelligence.

Meanwhile in further research in 2013, Harvey stated that managers who able to become world-wide supply chain managers are those glopatriate type, because he will be able to live for 10 years in rural areas far from their country.

Prajogo and Sohal (2013) tried to understand the competencies and skillset required by SC managers to manage global supply chain effectively. Communication and team works are the most critical competencies and skillset required by supply chain managers in future challenge. Supply chain managers have to own multiple skills to overcome various challenges in the futures, including cross cultural communication and the broad knowledge of technology.

Harvey (2013), Hohenstein, and Hartmann (2014) constitute an urgent demand to establish a global mindset in implementing the global supply chain in MNCs. The importance of global perspective is open mindedness and understanding of cultural diversity as a basis for global supply chain managers to be able to work in the midst of increasing globalization and growing target

market. Additionally Kiessling et al. (2004) adds that intangible asset is more needed compared to tangible assets for future strategic global success. The intangible assets that must be retained by the managers are global awareness, corporate strategy, cultural empathy, cross-cultural team building, global negotiation skill, and self-assurance.

Competencies are required by global supply chain manager according to researches that have been conducted. It is clear that the specific need related with global supply chain manager was not detailed. Study conducted by Harvey and Richey is already mentioned about the competencies of global supply chain manager, unfortunately the further detailed analysis or the scientific research using the quantitative was not available. Therefore, it is difficult to measure the requirement and competencies level. Prajogo and Sohal (2014) discussed the detail about the competency, but the studied competencies was combined with skill set, which are two different things. Therefore, further study is required to understand the required competency of global managers in managing the SCM in MNCs. Followed with empirical test to prove the hypothesis, so we can understand the most important competency required by global supply chain managers.

SOLUTIONS AND RECOMMENDATIONS

Based on the details above, it can be concluded that there is limited availability of study on the relation between HRM and SCM in the global company (global supply chain management). To be specific, competencies and skillset that are required to develop a global supply chain manager. The existing study results are limited to part of HRM – skill knowledge and abilities, selection, training and development, performance, and also education and teaching – while the other HRM activities related with recruitment, compensation,

labor relation, health and fair concern also global mindset were not studied in detail.

Studies that have been conducted merely done by the literature review or method qualitative, while the empirical studies are still very limited. The only quantitative study that has been conducted was done by Pajogo and Sohal (2014), but stop on the descriptive stage while the hypothesis testing with the quantitative complex has not yet been conducted.

To be global managers and MNCs are certainly not an easy job, it requires certain skill and competency, glopatriate, and global mindset, with that managers can adapt well in various cultures where companies operate. In the other hand, the management must ensure the compensation and the benefit package for managers to freely take the decision responsibly as global managers.

FUTURE RESEARCH DIRECTIONS

Based on discussion in this chapter, competencies that is required by global supply chain managers have been defined. However, deeper study is still need to be conducted on required competencies and skill set required by global supply chain managers.

Previous studies that have been conducted merely focus on literature review or qualitative study, there is no study yet which asses the required competency by empirical study or quantitative.

CONCLUSION

In this globalization era, companies are required to be able to compete in global level, in order to do that – companies have to produce products/ services with high quality and affordable price that affordable and companies operate under global perspective to gain cheaper raw materials, produce with lower cost, cheap labor, and distribute the products/services to all over part of the world with

competitive logistic cost and on time delivery. This can be happened only with the existence of global supply chain management which managed by global supply chain managers equipped with specific skillset, knowledge, competencies, abilities, training, development, and series of HR activities that.. Critical success factor for MNCs relies on the tangible and intangible asset, but the intangible asset contribution is much bigger.

Global supply chain managers are required to have competencies and skillset. Based on the details analysis on this chapter, we define several critical competencies of managerial competencies such as social knowledge, communication, and team works, and global awareness. Transformation-based competencies, and capability to adapt in various different environments.

KEY TERMS AND DEFINITIONS

Globalization: A network of contemporaneous events, options, and constraints, which requires the development of a systematic concept of supply chain strategy development and implementation.

Supply Chain Management: The integration of all the activities and processes associated with the flow of goods and information from the raw materials stage to the end consumer of the product/service.

Global Supply Chain Management: Network of facilities, activities, and social relationships that performs a multitude of integrated value-adding function in a global context.

Global Manager: A “leader” which is a group member whose influence on group attitudes, performance, or decision making greatly exceeds that of the average member of the group.

Multinational Company: A mix of competitive and comparative advantage, global advantage as the basis rather than geographical locations of the organization’s activities and the integration of activities across locations.

Discrete Event Simulation in Inventory Management

Linh Nguyen Khanh Duong

INTRODUCTION

Successful supply chain management aims to deliver the right products at the right time to the right place and in the right condition (Deniz, Scheller-Wolf, & Karaesmen, 2004). This is not a simple task, and many factors influence the success of the supply chain; perishability and substitutability characteristics of inventory are key attributes that cannot be ignored. Once produced, perishable products have a finite shelf life. When expired, they are either partially or wholly valueless. Perishability affects many industries (e.g., fresh food and chemicals). The more time that perishable inventory is in storage, the less time it is available for sale to customers. The combination of these factors often requires simulation models to be developed to understand the behavior of the system as the parameters change.

Product substitution is a possibility when considering multiple products. Research indicates that an alternative product is willingly chosen by customers if the preferred one is out of stock, and product substitution is important to companies (Chen, Feng, Kebliş, & Xu, 2015). Research shows that consumer-driven substitution due to product stock-outs common in the grocery industry (Bijvank & Vis, 2011). In a recent study, the Grocery Manufacturers of America estimated that approximately 70% of consumers who find a particular item is stocked out on the first occurrence will happily purchase another product (Grocery Manufacturers Association, 2015). van Donselaar,

Van Woensel, Broekmeulen, and Fransoo (2006) analyzed these types of situations and suggested that accounting for substitution while establishing inventory control policies could lead to a reduction in waste.

Holding inventory is necessary for a firm to fulfill customer orders; however, holding inventory also incurs holding cost (e.g., providing material storage and insurance). Each product has a holding cost applied to the average inventory level over a specified period, a selling price, and a cost per unit of stock. Managers must decide on the replenishment time and replenishment quantity for each item within product subcategory, to maximize expected profits under uncertain demand while minimizing the instances of running out of inventory (i.e., a 'stock out').

Determining the appropriate replenishment policy that will maximize profit under probabilistic consumer demand is known as stochastic optimization. In stochastic situations, it becomes difficult to formulate models accommodating so many factors. According to Lucas, Kelton, Sánchez, Sanchez, and Anderson (2015), a discrete-event simulation methodology is suitable to capture the dynamics of this problem. Discrete-event simulation involves modeling a system and where a specific event triggers a change in the state of the system. Such simulation allows tracking of specific items of inventory (e.g., when an item 'expires' it would trigger an event and a change in the system state); this is a necessary precondition that makes this type of simulation more appropri-

ate than continuous simulation for the modeling of substitutable and perishable inventory systems. Such simulations can also be used in the evaluation of new IT improvements that can be used to improve collaboration practices over the supply chain (Cannella, Framinan, & Barbosa-Póvoa, 2014). Simulation can incorporate stochasticity and complexity while providing detailed output for further analysis and optimization work.

BACKGROUND

In general, there are four types of perishable products: food items (e.g., meat, vegetables, dairy products, and beverages), medical/pharmaceuticals (e.g., vaccines, blood, and drugs), plants, and industrial/other (e.g., paint and chemicals). Each type may have several categories, subcategories, and product variants. For example, milk products can be divided into powdered milk or ready-to-drink milk products. Ready-to-drink milk products can be further divided into yogurt or drinks; then, by flavors and sizes.

Managers must decide the inventory level for perishable products to ensure customers have all desired products at the right time at minimal disposal cost. Managers want to provide the highest customer service level at the lowest cost. Some of these costs that play a significant role in perishable inventory management include ordering cost, holding cost, disposal cost and shortage/backlog cost. Nahmias (2011) gave a comprehensive review of the perishable inventory theory. There is two primary inventory management approaches, periodic review (monitoring inventory levels at fixed intervals) and continuous review (monitoring inventory levels continually). Periodic review has been widely used for a long time due to the relative simplicity of application; it involves the amount of inventory at a particular point in time and reviewing the inventory on a regular basis after that. For example, a store-person may count the inventory once per week and then calculate how much more inventory is required in the next

order. Contemporary approaches include vendor-managed inventory (VMI) and collaborative planning forecasting, and replenishment (CPFR) processes to improve multi-tier inventory management (Alftan, Kaipia, Loikkanen, & Spens, 2015).

A single period perishable inventory model the 'newsvendor' model; named for the 'newsboy' that would need to buy a stack of newspapers before shifting them to another location for sale to customers. The entrepreneurial newsvendor had to calculate the likely number of newspapers required; if too many were purchased, they would be worthless at the end of the day; if too few were purchased, they would lose potential sales (Nahmias, 2011). In real stochastic environments, where newsvendor models are most useful, managers must pay attention to planning models where there is greater age dependency in demand, consumers are sensitive to these factors, the products have a short shelf-life, and there is a risk of quality issues (Amorim, Costa, & Almada-Lobo, 2013).

To expand market share, many producers/distributors tend to provide more product lines, and many retailers opt to offer new choices for consumers by introducing new brands, more flavors or sizes of existing products, or new products with various attributes. Consequently, this creates additional managerial challenges as policies must account the effects of substitution and perishability. In consumer-driven substitution, the customer's willingness to substitute during a stock out is a major factor; in contrast, decision-maker-driven substitution involves a managerial decision to substitute a given product with a different variant of the product (Broekmeulen, Fransoo, Van Woensel, & van Donselaar, 2007). Many of these factors may be difficult to capture and 'price' in a meaningful way relative to other factors, often requiring some judgment when developing a model that seeks to minimize a total cost function. In contrast, many managerial situations require consideration of a broader range of metrics and KPIs (Cannella, Barbosa-Póvoa, Framinan, & Relvas, 2013; Cannella et al., 2014). This would also enable managers to include metrics that are

inherently more familiar to them and which are more comprehensible (e.g., average inventory levels). Having a relationship between metrics that are commonly used would make replenishment and inventory management models valuable over a wider range of decision-makers. Understanding the components to the model, and how changes to particular metrics they are familiar with will help the organization to achieve wider objectives, will help to influence behaviors at the divisional level, and allow improved alignment over multi-division metrics. Managers will also be able to rapidly and naturally adapt their management style if the replenishment policies are based on meaningful metrics.

Perishability relates to the deterioration of a product over time and is often associated with fresh food; a cut of meat will quickly ‘go bad’ if it is exposed to warmth and sunlight, creating food safety issues for consumers. Globalization has created a big change in consumers’ behavior as it has led to many people to seek superior quality foods, leading to increased trade in food products as some are produced in specialized locations. Supply chain management has become increasingly important as the volumes of perishable products from developing countries (e.g., Vietnam and Mexico) have increased; in particular, export volumes are expected to increase substantially when the Trans-Pacific Partnership is enacted (Executive office of the President, 2015).

A report from the United Nations shows that one-third of food, globally, is lost as waste; the solution to ensuring sufficient food for people around the world is to reduce food waste, rather than focusing on producing more (Scialabba, 2014). Another example is the loss almost blood platelet units (used in blood transfusions) that expire without being transfused - these expired units impose a significant financial burden on health services. Dynamic pricing strategies, influencing consumer behaviors, can improve overall profitability (Li, Zhang, & Tang, 2015); this can often lead to more comprehensive considerations of how the stock is managed and sold, with a focus on maximizing revenue rather than minimizing costs.

Therefore, the application of perishable inventory models provides higher customer service levels and lower waste.

The determination of replenishment and ordering policies to achieve requirements of perishable products is crucial but complex when there are stochastic demands. In such complex situation, stochastic simulation is an effective modeling tool. This chapter illustrates how simulation methods can be applied to the perishable inventory management system and outlines the advantages of using such simulation methods and provides future research opportunities.

THE USE OF SIMULATION IN CREATING POLICIES FOR THE MANAGEMENT OF PERISHABLE INVENTORY

Discrete-event simulation models can be developed to compare the performance of multiple systems. Through advanced search techniques in simulation, feasible solutions can be evaluated to obtain the best solution. This type of solution is not guaranteed to be optimal; however, the longer the search process is run, the higher the probability will be that the obtained result is optimal.

These models must be validated against real businesses where perishability is important (e.g., retailers, supermarkets). This critical step ensures that the model ‘works’ correctly and produces output that matches the output from the real business (Kelton & Sadowski, 2009); such validation provides confidence that the model will then prove to be useful when the parameters are changed.

The first step of a ‘simulation-optimization’ model is the design of simulation phase. There are four major events that occur in inventory management systems that work with perishable and substitutable products (Myers, 2009):

- **Update Inventory Age Event:** Here, the system will update inventory age for all products, update expired products, and schedule inventory aging in the next period.

Figure 1. Simulation: Optimization model

- **Order Event:** Here, the system will set order priority, update total unit order, schedule delivery, and schedule the next order.
- **Generate Demand Event:** Here, the system generates demand for each product and schedules the arrival time for orders in the next period.
- **Sales Event:** Here, in relation to perishability and substitution problem, this event establishes the preferred product and ranks substitute product to determine what sale is made, based on inventory availability.

After major events are defined, a selection of values of the parameters is determined for a range of operation conditions. Then the simulation - optimization model is run multiple times, and outcomes are recorded (Figure 1). The performance statistics are collected after a warm-up period determined by Welch's graphical procedure (Law & Kelton, 2000). The goal is to understand the impact of input parameters such as shelf-life, lead time, and substitution rules on the results. The optimization occurs by varying the parameters and then determining which parameters provide superior outcomes. These values of parameters can then be used by real managers in a real inventory system to achieve desired results.

The simulation - optimization model is designed to find the optimal solution based on the problem of choosing some factors that help to achieve the final goal. For example, the model designed by Myers (2009) aims to maximize the total profit for a retailer under customers' demand uncertainty. The optimal solution is based on choosing the 'order up to' level for each product.

Assumptions

This type of inventory model must account for a range of assumptions that closely mirror the situations found in real inventory systems. These include:

- **Shelf-Life:** The products are assumed to have a constant shelf-life.
- **Demand:** To use a simulation - optimization approach, using a discrete distribution is preferred.
- **The Profit Margin:** It is assumed that the profit margin for each product is the same although the price and unit cost can vary for each product.
- The replenishment lead time is deterministic.
- All products arrive into the system as 'new' products.
- Substitution is considered to be consumer-driven. For example, the customer considers to buy an apple with first preference is A brand, the second preference is B brand. The customer will look for fresh A brand first. If there is no fresh A brand, the customer will choose among four alternatives below:
 - Substitute with older A brand product if it is available.
 - Substitute with fresh B brand product if it is available.
 - Substitute with old B brand if no A brand is available, and no fresh B brand is available.
 - Decide not to buy either A or B brand product.

Model Verification and Validation

Verification ensures that the model is working properly and the logic of the model is correct. Validation then ensures that the model is an accurate representation of the real system (Sargent, 2013). The results of the model are compared with the actual system results from the past. Then the model results are discussed with managers to validate the model. Where discrepancies are observed critical errors in the model can be corrected. When a model is considered to be verified and validated, it can be used to help generate solutions to the managerial problems.

Model Results

The results from the simulation provide insight into the system performance. It shows how a simulation model helps to analyze the system's performance and establish solutions that will contribute to improving inventory system performance. The model can be run numerous times with a range of parameters. Each time some performance measures are calculated. These are collected over the numerous iterations of the model and are presented in graph and tabular forms. This presentation allows identification of the most appropriate parameters to use when managing the real inventory system; the best parameters will usually minimize or maximize certain performance measures. As an example, with perishable items, simulations would help us to establish what parameters are best able to provide outcomes that minimize the reduction in value of the inventory while maximizing sales due to substitutability.

This approach has been well-established as an appropriate method to manage inventory. Myers (2009) used a simulation model to analyze an inventory system with perishable and substitution, using the periodic review system. Myers (2009) found two essential components in the optimal order up to levels of the two products. The first element is the 'aggregate order up to' level of all the goods, which is converted to an

aggregate service level. The second element is 'allocation order up to' level for each product. The results were then used to develop a heuristic for establishing an inventory policy for perishability and substitution; heuristic techniques allow a problem to be rapidly solved but may provide a slightly non-optimal outcome. When age-based substitution level increases from low to high, the aggregate service level is increased no matter if the product-based substitution level is low or high.

Beshara, El-Kilany, and Galal (2012) used simulation methods to evaluate and analyze the performance of a replenishment model of agri-food supply chain for highly perishable products. They evaluated the system performance using the average purchasing cost/day, the average cost of waste/day, the average cost of selling in open market/day, the average holding cost, the average transportation cost/day, and the average of total cost/day. They established that the holding cost is the greatest cost, and the performance can be increased by decreasing waste and the amount of perished products at facilities. Including substitution flexibility can provide a significant improvement in costs, particularly by decreasing ordering costs (Seyedhoseini, Rashid, Kamalpour, & Zangeneh, 2015).

SOLUTIONS AND RECOMMENDATIONS

Simulation remains a powerful tool to understand and develop management solutions applicable to complex systems. Simulation models can accommodate many assumptions, especially relating to short-shelf-life products for which experimentation is expensive and risky. From detailed studies of a particular subsystem or wider studies of entire supply chains, simulation enhances our ability to create effective models of systems. Therefore, many scholars have turned to simulations to solve problems in these types of complex systems with stochastic demand and many input factors. They have also recognized that simulation allows sensi-

tive analysis of the effects of factors such as product based substitution, age-based substitution, lead time, shelf-life of products, cost structures, cost parameters, and some products on the simulated optimal solutions.

Myers (2009) used a simulation-optimization approach to analyzing inventory management systems that account for perishability and substitution. This approach allowed identification and evaluation of the impact of key factors in determining optimal policies. A heuristic approach for determining inventory policy for two product variants was developed after this.

Beshara et al. (2012) used simulation results to propose different scenarios to study the effect of order quantity on total cost. Their results were also used to analyze the contribution of each cost parameter (e.g., waste cost and holding cost) on total cost and the relationship between total cost and safety stock level. Another approach is to evaluate non-financial metrics and find a solution that balances the needs of multiple stakeholders (Duong, Wood, & Wang, 2015). Merely optimizing a single, combined financial metric has limitations, that can be addressed by evaluating a range of factors. As an example, many functional managers may need performance that is not effectively represented by using a total cost measure, but which may be captured by examining performance over a range of metrics (Cannella et al., 2013): Order Rate, Fill Rate, Average Inventory, Inventory Variance, and the Work in Progress (WIP) Variance ratio.

Simulation models provide a suitable method for developing new inventory management systems and approaches that will see wide application in current supply chain solutions. This use of simulation is an important use of information technology to solve significant management problems in the contemporary era.

FUTURE RESEARCH DIRECTIONS

Future research can extend models to account for questions that remained unanswered; e.g., optimal

ordering policies for fixed life perishables under continuous review (Nahmias, 2011). Such work would also extend Myers (2009)'s work that focused only on revenue as a performance measure and used a periodic review approach rather than a (more realistic) continuous review approach. The proposed future research would be based on more realistic assumptions (i.e., assumptions closer to those observed in real situations) than have been used in past studies, particularly emphasizing other decision-making criteria other than just revenue while adopting a continuous review approach. Cross-functional considerations and non-financial metric may be more easily assessed using simulation approaches (Duong et al., 2015). Real-time information (such as provided by radio frequency identification (RFID) technology coupled with enterprise resource planning (ERP) systems should be included as this is an area where research lags behind industry practice (Karaesmen, Scheller-Wolf, & Deniz, 2011, p. 429). Data from item-level tagging provides greater ability to manage these situations (Thiesse & Buckel, 2015). Future research can examine real-time information used in the context of issuing, pricing, and disposal strategies to extend current state-of-the-art inventory management systems (Lee, Mu, Shen, & Dessouky, 2014).

Future research will provide significant benefits for managers and society. Dynamic inventory management methods for perishable inventory should enable managers to reduce the incidence of stock-outs while improving other criteria. This research should reduce waste while enhancing business operations. Such outcomes are important globally as key inventory categories that suffer from perishability include pharmaceuticals and foodstuffs, which are of crucial importance in developing countries. The future research will help to reduce waste in these categories and ensure wider availability to the required products by many more people. By continuously improving inventory systems waste will be decreased, and the products will be more easily delivered to more customers. This may require consideration of

different KPIs that are more functionally based, indicating that simulation might enable development of more meaningful inventory management systems (Duong, Wood, & Wang, in press).

CONCLUSION

This chapter focused on solving problems relating to the management of perishable inventory due to the significant benefits globally that can be secured by reducing wastes accruing from deterioration. Effective ordering and management policies for perishability products can reduce the losses. Perishability and substitution inventory management systems with stochastic demands are very complex, making them most amenable to analysis using simulation as the use of analytical tools to model and analyze such complex systems remains impractical. Simulation enables models to be developed that can accommodate significant complexity and stochastic variation while generating a range of data that enables key relationships to be more clearly understood. The simulation data can be used to derive appropriate replenishment and inventory management policies that will enable organizations to reach any of a range of different objectives.

Research shows that discrete event simulation models are preferred for evaluating such complex inventory systems. This chapter showed that simulation can be used as a tool to determine optimal inventory policies accounting for perishability and substitution, particularly accounting for a range of non-financial metrics that functional managers may be required to use. The use of simulation is supported with optimization tools and simulation software and will prove increasingly important in scenarios, given the propensity of consumers to willingly substitute one product for another, increasing the complexity of management decisions. These models enable managers to understand complex interactions between perishability parameters and substitution (either driven by consumers or the managers) and the replenishment policy parameters.

KEY TERMS AND DEFINITIONS

Continuous Review System: A system where the stock level of each product is calculated each time a product is moved in or moves out the systems in real-time, triggering an order for more stock when the inventory level falls below a particular re-order point.

Optimization: A procedure to make a system or a process as efficient as possible. Optimization usually requires mathematical techniques to find the best possible solutions to a problem. In inventory management, optimization often relates to calculating how much inventory to hold (to meet customer demand) while holding as little as possible (to minimize the costs of holding inventory).

Periodic Review System: A typical inventory system where the inventory level is reviewed at

a regular time intervals (e.g., once a week), after that the decision is made as to how much to order to bring the inventory level up to a given amount.

Perishable Product: A product with short shelf life or one that easily deteriorates. These items include fresh foods, dairy products, and pharmaceuticals. This period of shelf life complicates the inventory management as they must be processed and move through the supply chain for sale to customers before they perish and lose either part of their value or their entire value.

Product Substitution: A possibility when considering management of multiple products. It is a case that a customer will substitute their preferred product with another with similar characteristics. This is particularly true with ‘commodity’ style products (e.g., milk, where two brands may have very similar characteristics of milk product).

Radio Frequency Identification (RFID): A system using radio frequencies to transfer data from tags on items to readers that are connected to other computer systems. This allows automatic identification and tracking products.

Simulation: A method to imitate the operations in real world system over time. The simulation requires a model that closely represents or replicates key characteristics of the physical system.

E-Business Supply Chains Drivers, Metrics, and ERP Integration

Jean C. Essila

Northern Michigan University, USA

INTRODUCTION

The world of business is witnessing the emergence of electronic supply chains (e-SC or e-supply chain). The Internet has radically changed the nature of supply chains at its core (Sambasivan, Mohamed, & Nandan, 2009). In fact, as more business is performed via the Internet, e-SCs are becoming an integral part of supply chain management (SCM; Gunasekaran, Patel, & Tirtiroglu, 2001; Sambasivan et al., 2009). Businesses are becoming supply chain-sensitive organizations. With business via the Internet requiring different fulfillment approaches, traditional drivers of regular supply chains are no longer adequate for explaining how and to what extent e-SC performance is driven (Sambasivan et al., 2009). E-commerce offers consumers more buying options than traditional business. Buyers can instantly compare prices, product attributes, and delivery parameters. As a result, customers have become increasingly demanding. The task of supply chain professionals is more complicated than ever because e-SCs rely on ERP software. This situation often leads to unsatisfied customers, which can force companies to close their doors.

SCM is responsible for ensuring that customer needs are satisfied in a cost-effective manner. To do this, they formulate strategies, allocate resources, organize activities, and assess performance. Effective and efficient SCM resource allocation is contingent upon a proper understanding and interpretation of its performance drivers (Stock & Boyer, 2009). However, managers often operate on the basis of their own experience and commonly-used methodologies that do not always result

in the desired level of performance. Therefore, a framework to leverage actual drivers of e-SC performance is needed (Caputo, Cucchiella, Fratocchi, Pelagagge, & Scacchia, 2004).

In fact, e-SCs involve partners that are linked by Internet technology in broad networks where customers, retailers, distributors, manufacturers, and suppliers are connected (Fliedner, 2003; Lightfoot, & Harris, 2003; Williams, Esper, & Ozment, 2002). Within and across the networks, actors collect, process, store, and disseminate information on materials, goods, funds, and services. e-SCs are composed of many-to-many connections, while relationships in traditional supply chains are characterized by one-to-one connections. A dramatic revision of current SCM techniques is needed (Caputo et al., 2004). Therefore, understanding e-SCM performance drivers and their integration with ERP becomes a necessity for any SCM professional. Based on the literature survey, little attention has been devoted to SCM performance driver evaluation despite the high volume of ongoing research in the field (Gunasekaran et al., 2001; Sambasivan et al., 2009).

This article discusses the performance drivers of eSCs, metrics for measuring efficiency, and their integration with ERPs. Considering the fact that e-SCs are becoming an integral part of the extended enterprise (Sambasivan et al., 2009), the first section of this article introduces a model of the traditional supply chain for both manufacturing and service systems. In addition, it assesses the logistical and cross-functional performance drivers of supply chains (Chopra & Meindel, 2010; Olver, Lant, Plant, Majeste, & Kursh, 2010). The section concludes with a brief comparison between physical product and information flow.

The second section examines e-SC structures and performance metrics for capturing and gauging system effectiveness and efficiency. It also explains the corresponding measures for the implementation of each metric. It should be noted that e-SC metrics and their corresponding measures are effective ways for managers to ensure that the supply chain is achieving the expected benefits (Riggins & Mitra, 2001).

The role of information technology has shifted from passive enabler to high-performing processes that directly impact the organization's performance. Because e-SC performance requires integration (Smart, 2008), the third section discusses the integration of ERPs into e-SCs to enhance their performance. In this last section, the author discusses the effectiveness and efficiency benefits of ERP for e-SCs (Sambasivan et al., 2009).

SCM is among the most important factors to organizational success (Gunasekaran et al., 2001). There are many benefits of e-SCs that are quantifiable and others that are not (Singh & Byrne, 2005). Effective SCM can enhance competitiveness and increase profitability. Nevertheless, SCM professionals and other actors must understand the factors that undergird driver performance in order to achieve a competitive advantage.

BACKGROUND

According to Stevenson (2012), supply chains are sequences of organizations involved in the production of a good and/or the provision of a service. The author argues that organizations generally consist of facilities, functions, or units, and carry out production or service provision activities. Therefore, their facilities, functions, and activities involved in the production or service provision are integral parts of supply chains. Facilities may include operating units, such as factories, storage facilities such as warehouses, processing centers, distributions centers, and even offices since information is manipulated to trigger, move, and track products and services within and

throughout the supply chain. As a result, every product is made through its supply chain within and across multiple sequential organizations. The main conceptual dilemmas have always been: (1) What activities and components of an organization should it include in its given supply chain? (2) Where are the boundaries of SCM territory?

The consensus today seems to be that the supply chain begins with the original suppliers of raw materials. This is followed by the production in an operating unit, the storage in processing centers and warehouses. It ends with the delivery of the finished item to the user. Therefore, supply chains existed since the creation of the first good. However, developing a consensus definition of a supply chain has not been an easy task for academicians and practitioners.

Stock and Boyer (2009) examined 173 unique definitions of SCM from systematic reviews of the entire decision science field in an effort to frame the adoption of a consensus definition of SCM. The definitions were considered unique because they added at least one new element that differed from existing definitions. This inquiry was performed based on the assumption that in the absence of a uniform agreed upon definition, it would be impossible to advance the SCM theory and practice (Stock & Boyer, 2009). The study identified three themes (activities, benefits, and constituents) associated with the definition of SCM. Six sub-themes were also identified. The theme titled "benefits" consisted of three sub-themes: value added, efficiency created, and customer satisfaction. These three sub-themes accounted for 47%, 35%, and 28%, respectively. The theme titled "activities" was credited with physical (materials), services, finances, and information flows counting as its first sub-theme, with networks of internal and external relationships as its second sub-theme. However, there continues to be a variety of theories on what is a supply chain and how SCM should be defined (Mentzer et al., 2001).

With the advent of the Internet and its business applications, the world has witnessed a new

Figure 1. Simple service supply chain (adapted from Fawcett et al., 2007) (Source: Essila, 2015)

type of supply chain, the e-SC. This added more confusion to the conceptualizations on SCM. Confusions upon definitions of SCM existed in both the academic and practitioner circles (New, 1997; Tan, 2001). This article is based on the existing literature in an attempt to frame a comprehensive understanding of the concept of an e-SC, its performance drivers, accompanying metrics, and integration with ERPs. A framework for structuring e-SC drivers helps to achieve a strategic fit between the supply chain strategy and the organization competitive strategy (Chopra & Meindl, 2010).

TRADITIONAL SUPPLY CHAINS

Models and Drivers

- Manufacturing and Service Supply Chain:** As mentioned, the Stock and Boyer (2009) study that compiled 173 unique definitions of SCM proposed a new consensus and encompassing definition of SCM. SCM is the management of networks of relationships within and throughout organizations consisting of suppliers of raw materials, procurement,

production units, logistics, and marketing that facilitate bidirectional flow of goods, services, funds, and information from the original supplier to the end-user with the benefits of adding value and maximizing profit while increasing customer satisfaction (Stock & Boyer, 2009). E-SCs focus on the management of the information flow, managing technology and information processes to optimize the flow of goods, finances, and materials to achieve customer satisfaction and competitive advantage (Srinivasan, 2010);

- Model of Manufacturing and Service Supply Chain:** Models are selected and used as simplified representations of reality. Models facilitate understanding of phenomenon or concepts. This section introduces models of traditional supply chains for both the manufacturing and service sectors. To illustrate supply chains, Fawcett, Ellram, and Ogden (2007) suggested the following simple models of manufacturing and service supply chains:
 - Simple model of a hotel service supply chain;
 - Simple model of a manufacturing supply chain.

Figure 2. Simple manufacturing supply chain (adapted from Fawcett et al., 2007) (Source: Essila, 2015)

As depicted in Figures 1 and 2, models of supply chains are viewed from the central ring of the chain (also known as the focal firm). The focal firm is the departing point to both the left and the right. Partner firms to the left of the focal firm form the upstream side of the supply chain. Those to the right form the downstream side of the supply chain. Upstream partners are also known as tier “n” suppliers. Most definitions in the literature describe supply chains as the flow of materials, information, services, and funds from the suppliers of suppliers all the way down to the final consumers. The flow is symbolized by arrows as depicted in Figures 1 and 2. Some authors argue that the essence of SCM is to manage the flow of goods and information from the point of departure to the point of consummation, implying a unidirectional flow (Arthur, 1991; Zsidisin, Jun, & Adams, 2000). In fact, information, materials, services, and funds all follow a forward and backward path through the supply chain (Svenson, 2002; Towill, Childerhouse, & Disney, 2001). Svenson explained that the demand information flows upstream from the consumers; materials, funds, and services flow downstream in the supply chain:

- Drivers of Traditional Supply Chains:** According to Olver et al. (2010), supply chain performance is driven by both logistic and cross-functional factors. Olver et al. (2010) argue that analyzing supply chain drivers helps to understand how organizations can improve their supply chain productivity to become more responsive and efficient. Logistics drivers are manufacturing and supporting facilities, inventories, and transportation. Supporting facilities are physical locations needed to provide a service (Fitzsimmons & Fitzsimmons, 2011). Hospital buildings, doctors’ offices, airplanes, or classrooms are examples of supporting facilities. Cross-functional drivers of supply chains are sourcing, pricing, and information. Information affects and is directly affected by all other drivers. It is, therefore, the biggest driver of a supply chain (Olver et al., 2010). Figure 3 depicts both physical and information flow in the supply chain.

Figure 3. Physical and information flow in the supply chain (adapted from Sherer, 2005) (Source: Sherer, 2005)

E-SCs VS. TRADITIONAL SUPPLY CHAINS

Structures, Drivers, and Measures

- e-SC:** e-SCs encompass partners that are connected by Internet technology in broad networks where customers, retailers, distributors, manufacturers, and suppliers are all linked (Fliedner, 2003; Lightfoot & Harris, 2003; Williams et al., 2002). Within and across the networks, actors collect, process, store, and disseminate information on materials, goods, funds, and services. e-SCs are composed of many-to-many connections while relationships in a traditional supply chain are characterized by one-to-one connections. A dramatic revision of current SCM techniques is needed (Caputo et al., 2004). The primary purpose of e-SCs is to help organizations increase effectiveness, improve efficiency, and achieve strategic benefits, such as revenue increase and competitive advantage, by establishing customer loyalty (Riggins & Mitra, 2001; Van Hooft & Stegwee, 2001). Next, the researcher introduces a structure of a typical e-SC;
 - e-SC Structures:** Wheatley (1999) predicted that in the realm of business, the amount of investment on brick and mortar facilities will be replaced by investment in technology. An increase in investment puts more pressure on e-SC managers to achieve high performance in order to yield a higher return on investment. Traditional arm's length, horizontal, and vertical integrated structures are no longer appropriate for e-SC since they connect organizations. Unlike traditional supply chains, "the electronic supply chain is round in form" (Williams et al., 2001, p. 708). The traditional supply chain goal is to increase responsiveness and efficiency through long-term stability. Traditional supply chains usually build relationships that can achieve a long-term benefit among partners. On the other hand, e-SCs are designed to adapt to the dynamic environment of an e-business. Therefore, they are flexible in nature. Supply chains shape the organizational structure for future performance enhance-

ments. As depicted in Figure 4, firms are connected through information technology. The focal firm is represented by a central ring. Other partners in the e-SC are represented by outer rings;

- **Drivers and Metrics of Traditional Supply Chains:** Unlike e-SCs, traditional supply chain design initiatives are generally viewed as top to bottom processes similar to the classical waterfall-type model in systems engineering. The examination of the six drivers, along with their corresponding metrics and accompanying measures, reveals the need for more stable relationships with partners. The advent of globalization and the Internet has dramatically changed the paradigms. Supply chain leaders need to adjust their strategies and structure the six drivers of traditional supply chains depicted (see Table 2) in order to achieve a high level of responsiveness while minimizing logistics costs to the entire supply chain;
- **Drivers and Metrics of e-SC:** As mentioned, drivers of traditional supply chains are facilities, transportation, inventory, information, sourcing, and pricing. They are classified as either logistical or cross-functional performance drivers (Olver et al., 2010). Unlike traditional supply chains, factors that affect e-SC performance are the

adapted organizational structure, which effectively manages relationships among network partners, the *managerial criteria*, and the e-SC *critical activities* (Caputo et al., 2004). Critical activities can, therefore, be viewed as logistical drivers. The organizational structure and managerial criteria can be viewed as cross-functional drivers of the e-SC factor equation.

Due to their unique characteristics, e-SCs need new metrics to adapt to challenges using innovative solutions that take into account the new dynamic environment (Barnes & Hinton, 2007). Little attention has been given to supply chain metrics and their accompanying measures (Sambasivan et al., 2009). Effective SCM requires an optimal balance between responsiveness and efficiency. Because each driver interacts with the others, supply chain managers must effectively combine the logistical and cross-functional drivers to avoid conflicting goals (Olver et al., 2010). From a practical perspective, the working technique is to increase positive impacts while minimizing the negative effects on the entire logistics system. A strategic alignment between the supply chain strategy and the organization competitive strategy is also important. Since competitive strategies support corporate strategies, the necessary strategic alignment becomes a central nerve for e-SC performance.

Figure 4. The e-SC structure (adapted from Williams et al., 2002) (Source: Williams et al., 2002)

Table 1. *e-SC metrics and their accompanying measures (developed based on Caputo et al., 2004; Sambasivan et al., 2009)*

Driver Type	Drivers	Metrics	Measures
• Logistical	• Adapted organizational culture	• Web-enabled service	• Data access time • System response time • Data transmission speed between business-to-business applications • Number of system verification steps • Traffic volume per page and/or site
• Cross-functional	• Managerial criteria	• Transaction reliability	• Number of transaction errors • Number of backlog transactions • Number of partners accessing the system • Cost per transaction • ERP interface cycle time
• Cross-functional	• Managerial criteria	• Cost	• Administrative cost • Administrative cost
• Cross-functional	• Critical activities	• Time	• Administrative time • Number of stages in the purchasing cycle • Purchasing lead time • Procurement cycle time • Procurement response time
• Logistical	• Adapted organizational culture	• E-Response	• Reliability of mail service • Completed number of transactions per period (day, week, or month) • Pending number of transactions per period (day, week, or month)
• Cross-functional	• Adapted organizational culture	• E-Invoice process	• Number of steps involved • Dispute resolution completion time
• Logistical	• Adapted organizational culture	• E-Payment	• Payment time • Reconciliation time
• Cross-functional	• Managerial criteria	• E-Document	• Data accuracy • Data reliability

In SCM, metrics track and gauge performance of each driver, as well as the impact resulting from its interaction with the others. Sambasivan et al. (2009) suggested six practical metrics for e-SCs: Web-enabled service, data reliability, time and cost, e-response, invoice presentation and payment, and e-document management. e-SC metrics capture performance both at the aggregated and organizational level. The aggregated level measures the performance of the entire supply chain, encompassing all partners to the supply chain. The organizational level focuses on individual organizational performance, including the process and the performer levels. The accompanying measures for each performance metric are summarized in Table 1. It provides a summary of the three e-SC drivers, in addition to their metrics and measures.

Information is the key driver of both traditional and e-SCs because it serves as the connector to all drivers (Olver et al., 2010). Information affects and is affected by all supply chain drivers. It triggers logistical and cross-functional processes associated with supply chain performance factors. For example, information on customer demand is the basis for the aggregate plan that establishes operation capacity. The operation capacity and capability dictate the rules for establishing schedules for specific products or groups of similar items. At this planning stage, basic strategies are formulated to meet demand using a chase demand or level capacity strategy.

At every stage in the supply chain process, bi-direction flows of information play a critical role. As a leading performance driver, informa-

Table 2. Drivers, metrics, and measures of traditional supply chains (developed based on Olver et al., 2010)

Driver Type	Drivers	Metrics	Measures
• Logistical	• Facilities	• Design capacity • Effective capacity • Capacity cushion • Utilization • Efficiency • Product variability	• Production per unit • Production cycle time • Flow time • Flow time efficiency • Production service level • Average batch volume
• Logistical	• Inventory	• Inventory cycle • Safety stock • Product availability • Obsolescence	• Average inventory • Inventory turns • Average replenishment lot size • Rate of obsolete inventory
• Logistical	• Transportation	• Network design • Shipment • Transportation mode selection process	• Inbound cost per period • Outbound cost per period • Inbound average shipment size • Outbound average shipment size • Volume per mode
• Cross-functional	• Information	• Demand forecasting accuracy • Process design type (push vs. pull) • Sharing and coordination • Availability • Accessibility • Enabling technology (ERP, EDI, RFID, and SCM) • Encryption	• Mean absolute deviation (MAD) • Mean squared error (MSE) • Forecasting horizon • Frequency of update • Information velocity • Transactions per users per enabling technology • Reliability of enabling technologies
• Cross-functional	• Sourcing	• In-house/outsource rate • Supplier selection • Purchasing/Procurement • Quality of supply	• Average purchasing price • Purchasing range • On-time deliveries to total deliveries • Receipts defect rate (RDD)
• Cross-functional	• Pricing	• Price menu • Profit	• Range of sale price • Average sale price • Incremental fixed/variable cost per unit

tion sets the stage for potential productivity gains for both logistical and cross-functional processes within, across, and throughout the entire supply chain. Information is a cross-functional driver of a supply chain (Oliver et al., 2010). As depicted in Table 2, information is a major supply chain driver of traditional and e-SCs. All supply chains often rely on enabling technology such as ERP, electronic data interchange (EDI), radio frequency identification (RFID), and SCM software. For e-SCs, enabling technology is a necessity. Such technology enables organizations to collect, store, process, and disseminate information within and across the entire supply chain. Next, the article will explain the necessary integration between e-SCs and ERP.

E-SC INTEGRATION WITH ERP

ERP Integration

ERPs, the third generation of enterprise systems (ESs), began with material requirements planning (MRP) in 1964. This was followed by manufacturing resource planning (MRP II) in 1983. ERPs are currently the most complex version of ESs to integrate both the functional and cross-functional process in the organization. ERPs have MRP as their core system. ERPs support all business function operations and transactions, linking them in a uniform platform to make information available in real-time across

Figure 5. Enterprise application suite in the supply chain (adapted from Magal & Word, 2011) (Source: Magal & Word, 2011)

the organization's entire supply chain. ERPs track the information within and across organizations. The Internet provides a broad visibility of the information. Supply chain managers utilize information provided by ERPs as the basis for making informed decisions.

A close look at an ES application suite reveals the necessity to integrate ERPs with SCM software. As depicted in Figure 5, the five basic components of a simple ES are the product life cycle management (PLM), the supplier relationship management (SRM), the ERP, the SCM, and the customer relationship management (CRM). ERPs are the epicenter of ESs because they integrate and connect the other ES components.

ERP systems are configurable ESs designed to integrate processes and information within and across organizations (Kumar & Van Hillegersberg, 2000). ERPs allow organizations to automate repetitive tasks, underlining transactions and processes. If properly used, SCM can be improved by integrating ERPs. Organizations that are best placed to succeed are those that have implemented an adequate business infrastructure utilizing ERP capabilities (Srinivasan, 2010). ERPs help to increase velocity in the supply chain fulfillment process.

FUTURE RESEARCH DIRECTIONS

This article identified variables relevant to the measurement of an effective e-SC. A similar study with more focus on the relationship among e-SC performance drivers that would allow a moderate (or even excessive) interference with a purpose of establishing a more elaborate causal relationship would provide more insight into the underlying construct. A longitudinal field experiment on the subject would also derive more detailed information about performance drivers of e-SCs.

Research could also be directed toward testing the hypothesis about the quality of enabled-technology used in an e-SC, as well as its effect on both efficiency and responsiveness. Suggested questions and ideas include:

1. Does full use of technology in the e-SC lead to greater effectiveness and a higher return to stakeholders?
2. What factors influence how supply chain professionals feel about the full use of technological supply chain capability?
3. If an entirely automated e-SC system was possible, would it be more effective?
4. Research could look more closely at traditional supply chains and technologically-

assisted e-SCs to elaborate a classification of technologically-assisted e-SC systems with a measure of the extent or magnitude of technology involved.

CONCLUSION

With the advent of globalization and the emergence of e-business, e-SCs are imperative. Organizations now compete using marketing, operations, and supply chain functions. Companies are no longer competing as stand-alone entities in today's business dynamic environment (Lambert & Cooper, 2000).

This article reviewed the six performance drivers of traditional supply chains based on the Olver et al. (2010) framework: facilities, inventory, transportation, information, sourcing, and pricing. The first three are referred to as logistics drivers because they are directly responsible for moving materials, funds, information, and service throughout supply chain pipelines. Information, sourcing, and pricing are known as cross-functional drivers of supply chains because they involve many business functions and processes. Traditional supply chain drivers aim to build long-term relationships among partners. They involve one-to-one relationship types. Early supply chains were arm's length and horizontally and vertically integrated in nature.

The emergence of the Internet and e-business calls for new types of supply chains—the e-SC. Unlike traditional supply chains, e-SCs are round in nature (Williams et al., 2001), and involve a many-to-many relationship among its partners. An e-SC initiative is designed to adapt to a dynamic environment. Therefore, they strive for flexibility and adaptability. e-SCs also require more enabled-technology than their traditional supply chain counterparts. As a result, performance drivers of traditional supply chains are no longer appropriate when explaining e-SC performance. Also, business via the Internet requires different fulfillment approaches, making traditional drivers of regular

supply chains no longer adequate for explaining how and to what extent e-SC performance is driven (Sambasivan et al., 2009).

A dramatic revision of current SCM techniques is needed (Caputo et al., 2004). Based on the framework suggested by Caputo et al. (2004), this article introduced three e-SC performance drivers: the adapted organizational structure for effectively managing many-to-many relationship types among network partners, the managerial criteria, and the e-SC critical activities. Enabled-technology employed by e-SCs are specific ESs such as ERP. ERPs are the third generation of ESs that began with MRP and MRP II. Effective integration of ERPs into e-SCs can significantly improve responsiveness and yield a high return on investment. Understanding drivers of e-SCs helps managers to better structure drivers to achieve their desired level of service at a minimal cost while increasing customer satisfaction and competitive advantage.

KET TERMS AND DEFINITIONS

Logistics: That part of SCM responsible for moving materials, funds, information, and services from the point of origin to the point of consumption.

Logistics Capabilities: Ability to employ logistics capacities to achieve the desired level of responsiveness at the lowest cost possible.

Logistics Capacities: This includes physical assets, such as buildings, plants, factories, manufacturing centers, processing centers, distribution centers, and warehouses, utilities, human resources, computers, cars, trucks, trains, aircrafts, ships, materials and goods, and supporting information.

Logistics Protocol: Sequence in which logistics activities are to be performed according to specific mathematical models.

Strategy: Set of actions designed and employed to achieve goals.

Supply Chain Facilities: Operating units (such as factories), storage facilities (such as warehouses), processing centers, distributions centers, and even offices since information is manipulated to trigger, move, and track products and services within and throughout the supply chain.

Supporting Facility: Supply chain facility necessary before a service can be provided (i.e., hospitals building, classrooms, airplanes, etc.)

Ecological Performance as a New Metric to Measure Green Supply Chain Practices

June Poh Kim Tam

Yudi Fernando

Universiti Malaysia Pahang, Malaysia

INTRODUCTION

Sustainable development has become a focus nowadays by governments, companies, communities, and even individuals. Manufacturing industry is the first to receive the brunt of criticism as manufacturing activities are assumed to be the prime culprit in creating environmental issues (Gunasekaran & Spalanzani, 2012). Massive consumption of natural resources and energy speed up the resources depletion rate which could scarify the needs of future generation for today's economic developments. Waste generation from manufacturing activities could create negative impacts like various pollutions to environment which subsequently hinder the operation of eco-systems (Cordoba & Veshagh, 2013).

Manufacturing companies are moving towards green oriented approaches in mitigating environmental issues. Green supply chain management is one of the approaches to address the relationships between supply chain management and natural resources management (Simao et al., 2016). According to Srivastava (2005), he defined green supply chain management as integration of environment thinking into supply chain management. Green supply chain initiatives included product design, materials sourcing and selection, manufacturing processes, logistics and distributions and product end of life management. Hawken et al. (1999) predicted a new industrial revolution that will be based on efficient use of resources. Today, the prediction has come true as eco-efficiency

based strategy is now widely adopted by business organizations, especially manufacturing industry.

Manufacturing companies need a comprehensive evaluation system to measure the outcomes of the green supply chain activities that implemented. Anbumozhi and Kanda (2005) found that most of the developing countries remained to be the traditional command-and-control or end of pipe solutions which is very passive approach to reduce negative environmental impacts after they are created. This is because business benefit is the first priority to be considered in adoption of green supply chain practices. Balance between environment and economic is important to a company survival.

BACKGROUND

World Business Council for Sustainable Development (2000) defined eco-efficiency as delivery of competitively priced goods and services that satisfy human needs and bring quality of life while progressively reducing ecological impacts and resource intensity throughout the life cycle to a level at least in line with Earth's estimated carrying capacity. In short, eco-efficiency means creating more value with less impact. It is a concept that combines both economic and environment management. Managers will be motivated to engage in environmental management if the green supply chain initiatives can achieve both environment and economics performance at the same time.

DOI: 10.4018/978-1-5225-2255-3.ch465

Current environment performance focuses more on environment impact intensity and resource use intensity by the firms. Although there is positive linkage between environment performance and economics performance, however it varies between firms. Ecological performance could bring more solid outcome measurement of green supply chain initiatives at market level (Boons & Wagner, 2009). According to Hart (1995), a company can build competitive advantages via natural environment management. Besides being cost effective, integration of natural system into business core value can help a company to have continuous improvement in aspects like quality and flexibility which can preempt competitors and appears as market leader in the manufacturing industry.

Therefore, the scope of performance measurement should be extended to wider indicators other than monetary factors. Besides cost reduction, Eltayeb, Zailani, & Ramayah (2011) suggested operational performance can be investigated from the perspective of quality, flexibility and delivery. In business context, organization has to be responsive to customer requirement in cost reduction, flexibility and quality product. Nowadays, supply chain responsiveness is not limited to business needs but environment needs as well. Supply chain responsiveness has to be designed

with green concept incorporated which efficient to both economic and environment. The benefits brought by green supply chain initiatives are not constraint to the focal company manufacturing activities. Instead, it can be extended into wider scope so that more and more parties can enjoy the benefits.

An exploration in ecological performance should be carried out so that a more holistic performance measurement is developed to assist managers in decision making of adoption of green supply chain initiatives. This study is aimed to discuss the concept of ecological performance which extended from environmental performance.

ENVIRONMENT PERFORMANCE

Commonly, manufacturing companies measure environment performance in term of environment impact intensity that caused by human activities and resource use intensity (Bran et al., 2011). Environmental impact intensity covers emissions to water intensities, emissions to air intensities and GHG emissions intensities. While resource use intensity covers water intensity, energy intensity and materials intensity in a process. Table 1 shows the indicators used to measure environment performance in monetary form by various sectors.

Table 1. Indicators of environment performance in monetary measurement (Department for Environment, Food and Rural Affairs of UK, 2006)

Indicators	Resource-Use Intensity	Environmental Impact Intensity
Economy-wide	Water intensity (m ³ /GDP) Energy intensity (J/GDP) Land use intensity (km ² /GDP) Materials intensity (DMI/GDP)	Emission to water intensities (t/GDP) Emission to air intensities (t/GDP) GHG emissions intensities (t/GDP)
Manufacturing	Water intensity (m ³ /GDP) Energy intensity (J/GDP) Materials intensity (DMI/GDP)	CO ₂ intensity (t/GDP) BOD intensity (t/GDP) Solid waste intensity (t/GDP)
Industry	Water intensity (m ³ /GDP) Energy intensity (J/GDP) Materials intensity (DMI/GDP)	CO ₂ intensity (t/GDP) Solid waste intensity (t/GDP)
Agriculture	Water intensity (m ³ /GDP) Energy intensity (J/GDP) Land use intensity (km ² /GDP) Materials intensity (DMI/GDP)	CO ₂ intensity (t/GDP) CH ₄ intensity (t/GDP)

Rosen & Kishawy (2012)	Sustainable manufacturing and design: Concepts, Practices and Needs	- VOC emissions	Environment performance contributed to economics performance via cost reduction in VOC emissions management

There are a large number of research about the relationship between environment performance and economics performance. Table 2 summarized some articles by authors from different countries to investigate if there is similarity on the findings. The outcomes may be influenced by other factors like culture, rules and regulations of the individual country.

Based on the content analysis of above articles, environment performance has positive influence towards company operational and financial performance. A good environment performance will benefit company by costs avoidance such

as reduction of materials and energy cost, waste management cost and treatment cost of emissions (Boons & Wagner, 2009). Although it is a positive linkage between environment performance and economics performance, environment performance is not holistic to measure the outcomes of green supply chain initiatives. The effectiveness is constrained to firm profit maximization and pollutions prevention and constrained to the individual firm context. Furthermore, there is considerably variation between companies. Zhu et al. (2007) claimed that different manufacturing industry types display different levels of GSCM outcomes.

Achievement of economic performance through cost reduction in waste and emissions treatment is viewed as end-of-pipe approach which may result in extra environmental investments. This would increase marginal cost as production cost is increased now (Boons & Wagner, 2009). Prevention and restoration efforts are costly and they go against the basic principle of economics. Managers can choose to control pollutions or maximize profits however the former can be only achieved at the expense of the latter. This implies that investors is hardly to invest in a company that is likely to be profitable and environmental oriented at the same time (Boons & Wagner, 2009).

Such notion should change as a company in fact can be profitable and at the same time protects its environment. It is depending on which system level and what kind of research objectives both the economic and environment performance are assessed at. Economic performance is the most important motivator why managers seek to implement green supply chain initiatives (Zhu et al., 2013). Besides costs, it has to be something else that can promote the company in order to outperform its competitors. Therefore, manufacturing companies need a performance measurement with more dimensions that can satisfy both economic and environment needs.

Nevertheless, the environment performance indicators still relevant at firm level as the cost reduction in environment performance still can motivate managers to continue look for opportunities within firm in justifying the business case that related to environmental management.

ECOLOGICAL PERFORMANCE

Ecologists concerns the natural resources that are available throughout an environment. The main focus of ecologist is to study the way how different ecosystems run, and the impact that inhabitants have on the amount of natural resources available. Business activities especially manufacturing industry can pose significant threat to environment

like CO₂ emissions, solid waste and ecosystems like excessive consumption in resource, water and land (Thoo et al., 2015).

Ecological performance is an extended version of environment performance with intention to cover more dimensions in measuring the outcomes of green supply chain initiatives. The concept of reduction of resource consumption and waste generation is not limited to focal company manufacturing activities but its strengths can be extended into other areas which benefits more people, either directly or indirectly. Ecological performance aims to measure green supply chain initiatives outcomes at market level and consumption system throughout the product life cycle.

Eco-efficiency is designed in all stages of product life cycle from materials extraction through production, consumption, recycling, and eventually waste disposal (Rosen and Kishawy, 2012). The reduction of ecological impacts should occur at every stage of product life cycle and the resource efficiency and waste minimization should perform up during the product usage even at the end life of the product. The continuity of eco-efficiency from manufacturer have to transfer to user and the reduction of ecological impacts should widely dispersed rather than individual firm.

A market driven system encompasses the firms that competing for the same customer base (Johnstone, 2007). Besides the two performance indicators discussed in above, manufacturing companies can build up more competitiveness through green supply chain initiatives. Continuous improvement in aspects of quality and flexibility would increase company's capabilities in responding to market dynamic changes. High responsiveness could help company to preempt competitors thus appears to be order winner in market.

Quality

The scope of quality is wide. It covers not only the product or service quality but also supplier quality, production quality, workforce quality as well as environment quality (Baumann & Genou-

laz, 2014). In traditional supply chain, evaluation of quality is mainly focus on product or service quality. Customers seek quality as the ability of the product or service to meet their expectations (Vachon & Klassen, 2008). With the increasing awareness of environment management, customers are now demanding more than the product quality. They are interested in knowing the materials used to build the product, would the production activities cause any negative impacts to environment, and what impacts that will product cause during its usage and what kind of the disposal needed when product is end of life. Life quality is equally important here.

Quality is not limited to focal company activities in supply chain. It is can be extended to suppliers and distributors as they are important players in quality management as a whole. This is crucial especially in the efforts of environment quality management. A company is not able to achieve sustainability without collaboration with its partners in the supply chain. Therefore, the scope quality management should be revised to include stakeholders that involved in the supply chain. The stakeholders could be suppliers, distributors, forwarders as well as employees.

A quality product is produced from a quality production. A production which is stable and within control always gives high quality on manufactured goods or service provided. The product meets the specifications and gives satisfaction to end users. Quality product can easily gain customer loyalty for long term business opportunity. Quality is a field that is less common in term of performance however it is worthy to extend the study in this area as it is a competency to company to compete with competitors (Vachon and Klassen, 2008).

Flexibility

Flexibility refers to how flexible a company can work in different ways, at different times, or in different places when it is necessary (Cambridge

Business Dictionary, 2016). Flexibility covers supplier flexibility, supply flexibility, production flexibility and delivery flexibility (Baumann & Genoulaz, 2014). Flexibility is important in a responsive supply chain. A flexible company has ability to react to customer change and deliver to customer in the soonest time.

Since always, researchers claimed that efficiency supply chain strategy and responsive supply chain strategies are used differently based on the product characteristic, functional and innovative (Fisher, 1997; Christopher & Towill, 2001). To be flexible, companies will keep high inventory in raw materials or finished goods so that they are ready if there is any changes or additional demand from customers. However, this is contrast to green philosophy. Besides materials, companies have to ensure the technology and processes used are flexible enough to cater the business uncertainty. It is a big challenge to company to have efficiency and flexibility exist concurrently.

Efficiency promotes to keep low inventory as low as possible, and try to avoid frequent machine conversion that could cause material and energy wastage. Flexibility is contradicted to concept of efficiency. It is really not easy for companies to balance between flexibility and efficiency especially when environment management comes into picture. Companies need a comprehensive consideration in decision making in order to sustain in both economic and environment developments. There is no one best single supply chain strategy that can meet customer's requirement. Therefore, leagile supply chain strategy was developed by Mason-Jones at al., (2000) by combining some elements of both strategies to fill the gaps. Leagile is using make-to-stock strategy/lean for high volume and stable demand products while make-to-order/agile strategy for everything else. This approach increases the flexibility in production capacity to meet demand upside or unexpected requirement. It helps company to achieve eco-efficiency without impacting company responsiveness.

Consumption System

Resource and energy consumption covers total ecosystems and cycles that impact earth conditions (Esty and Winston, 2006). Worldwide population continues growing and estimated to reach 8 billion by 2024 (United Nations, 2004). As at 2015, population has made a breakthrough of 7.3 billion. The population rapid growth rate increased the demand for commodities. The consumption volume and patterns influence heavily the ecological sustainability. As stated in World Wildlife Fund: Living Planet Report 2000, total global consumption of natural resources has risen by fifty percent since 1970, while earth's natural wealth has decreased by over thirty percent. This was due to the population growth and increase in consumption of many parts of the world. The humanity burden on earth is increasing however it was not corresponding increase in earth's bounty of natural resources.

Industry ecology has emerged with intention to reduce the ecological impacts by manufacturing industry. Industry ecology systematically examines local, regional, and global uses and flows of materials, and energy in products, processes, industrial sectors, and economies (Lowe, 2001). It metaphors manufacturing systems as natural systems to have capabilities to reuse the waste generated from one process as fresh input for another process. Hence, fewer resources extracted and minimal waste generated. This contributed to ecological sustainability.

Resources efficiency means the amount of the goods that come as a consequence of the spending of item resources (UNEP, 2010). This strategy measures the productive utilization and decrease of resources extraction from nature (Cordoba & Veshagh, 2013). The upgrade of 3R (reduce, reuse and recycle) concept to 6R (reduce, reuse, recycle, redesign, recover and remanufacturing) helps to enhance resources efficiency.

The purpose of introduction of 6R (reduce, reuse, recycle, redesign, remanufacture and refurbish) concept into a product life cycle is

to achieve a condition of a perpetual material flow, which help on minimization of that product ecological footprint (Jawahir, 2006). Besides, 6R concept simplifies and prolongs the product life cycle which could provide satisfaction to environmental oriented customers which may later translate to customer loyalty and better financial performance. 6R applies to product from external like customer return and distribution return as well as from internal like rework, scrap and end of life (Shaharudin et al., 2015).

In the past, the consumed products will be disposed of at their end of useful life. This cradle to grave product life cycle system has shifted to cradle to cradle type when organizations realized that proper return product management potentially generate higher profitability and provide opportunity for sustainable development (Shaharudin et al., 2015). Reverse logistics involve taking back the used or returned products for the purpose of reuse, remanufacture, recover, redesign, recycling and safe disposal of the product or materials (Eltayeb et al., 2011). The 6R concept is the most broadly used strategy in reverse logistics. Reverse logistics is applicable internally and externally. The waste substance that created during manufacturing process can be transformed into usable items via internal reverse logistic. The products that collected back from external could be unwanted used products from customers, end-of-life products and defective products from customers.

A firm that concerns about ecological impacts and the benefits of stakeholders is a firm that possesses specific capabilities which make the firm to be more competitive than its competitors. The ecological performance not only enhance economic performance in term of cost reduction and environmental impact minimization, the most important with the competitiveness built up the firm could progress and continue to sustain in market. Firm can build up the green image and create customer loyalty for sustainable developments.

The below table lists out parameters of environment performance that currently in use vs the ecological performance that proposed to be used

Table 3. Comparison between ecological performance and environment performance (Boons & Wagner, 2006)

Item	Environment Performance	Ecological Performance
Performance Variable	- Environment impact intensity - Resource use intensity	- Environment impact intensity - Resource use intensity - Quality (product quality, process quality, workforce quality) - Flexibility (delivery flexibility, production flexibility, supply flexibility) - Consumption system (energy use intensity during usage, recyclability)
System Level	Firm	Market
Boundaries	Individual firm	Firms that competing for same customer base
Linkage to economic performance	Profit maximization via resource consumption and waste reduction	Build up competitiveness to outperform the competitors. To be market leader in term of cost effective, quality, flexibility with leading capabilities
Motivation to Managers	High resource and production efficiency will enhance operational performance and financial performance	Proactive and value added to boost up company's competitiveness in market. Enhancement on company green image and create customer loyalty

in future. The ecological performance matrix apparently covers wider scope and more persuasive to manufacturers in adopting environmental strategies into business activities.

SOLUTIONS AND RECOMMENDATIONS

According to Bey et al. (2013), the main barriers that stop manufacturing companies from implementing environmental strategies are due to a lack of information on environmental impacts, expert knowledge, and allocated resources like manpower and time. These signify that a company would need to invest before the environmental strategies are implemented. Due to the pressure from customers and legislations, many manufacturing companies had started to engage business activities with sustainability efforts. Managers need more information and a justifiable performance measurement metrics to help them to make decisions in implementing the sustainable initiatives (Szekely & Knirsch, 2005).

Manufacturing companies have to ensure a balance tradeoff between environment and economic. They will be more proactive in adopt-

ing environmental strategies if the initiatives implemented can benefit them in wider scope. Besides reduction in environmental impacts and materials and energy consumption, there are other dimensions that can be included into performance measurement metrics.

A holistic performance metric should contain all three elements of sustainable developments: ecological, economic, and social. Economic metrics can be gross margin, return on investment, cost savings, and customer satisfaction. Ecological metrics can be CO₂ emissions, waste output, resources and energy consumption, and volume of pollutants. Social metrics can be employee satisfaction, community initiatives and ratings by publicity.

FUTURE RESEARCH DIRECTIONS

The ecological performance should be proliferated to developing countries. Economic performance is the most important motivator in encouraging companies to adopt environmental strategies. Anbumozhi and Kanda (2005) found that most of the developing countries remained to be the traditional command-and-control or end of pipe

solutions which is very passive approach to reduce negative environmental impacts after they are created. This is because business benefit is the first priority to be considered in adoption of green supply chain practices. Companies are preferable of conventional technologies and products that have been tried and tested. Besides that, the adoption of green supply chain management practices also subject to affinity for short term rather than long term operational benefits among development stakeholders (Ankrah et al., 2013).

CONCLUSION

The dimensions of performance measurement is subject to the important level of issues that managers would deal with. If the issue is limited at firm level, then information needed by managers would be simple thus less performance measurement dimensions are needed. If the consideration is at market level, then more performance measurement dimensions are needed in helping managers to make decision which is effective for overall business and ecological outcomes. A company has to continuously build up competitiveness to outperform the competitors in order to be market leader in term of cost effective, quality, flexibility with leading capabilities. Enhancement on company green image and create customer loyalty are part of the company business strategic management. Thus, ecological performance should be explored as a new metric to measure green supply chain practices.

KEY TERMS AND DEFINITIONS

Company Competitiveness: The ability of a company to preempt the competitors in the same market and continue to be market leader.

Eco-Efficiency: A strategy that emphasize on resource and energy optimization and waste minimization. It advocates balance development between economic and ecology.

Ecological Performance: A measurement metric that used to measure and numerically marking the impacts towards ecological and economic sustainability by a series of human activities.

Environmental Performance: A measurement metric that used to quantify the environmental impacts intensity caused by anthropogenic activities.

Green Supply Chain Management: Supply chain management that integrated environmental element into the flow from upper stream to downstream. Green supply chain activities including green purchasing, green manufacturing, green logistics, green distribution and reverse logistics.

Industry Ecology: A study about manufacturing activities and their impacts towards ecosystems and ecological sustainability. Its intention is to find ways to mitigate the issues aroused by manufacturing activities.

Resource Efficiency: A cradle to cradle approach in managing the useful life of extracted materials. The materials can be recycled to different forms to extend its perpetuality.

Sustainable development: Developments that are balance between economic, environmental and social. Economic developments should not built upon the sacrifices of human and other living things on the earth planet.

E-Commerce in Logistics and Supply Chain Management

Yasanur Kayikci

Turkish-German University, Turkey

INTRODUCTION

The rapid development of computing services and information and communication technologies (ICT) in the 1990s has dramatically transformed the way how organizations use logistics and supply chain operations for achieving competitive advantage. This has led to the emergence of the e-commerce context (Turban, et al., 2007; Harris et al., 2015). Gaining a competitive advantage in e-commerce means finding a balance of the right item price, customer service and delivery time, therefore e-commerce includes innovative and highly scalable e-commerce platforms (Chen et al., 2012). The impact of e-commerce covers both business-to-business (B2B) and business-to-consumer (B2C) transactions. Simply to point out, e-commerce is conducted through the Internet computer network products, trading, payment and services and other economic activities, and also it integrates all inter-company and intra-company functions, meaning that the three flows namely, physical flow, financial flow and information flow of the supply chain are affected by e-commerce.

The digital revolution has driven the development of e-commerce. Early applications can be traced back to the 1960s, but e-commerce only became popular in the 1990s due to the widespread use of the Internet. E-commerce uses communications such as EDI, POS, electronic ordering system, electronic mail, file transfer, video conferencing, workflow or interaction with a remote computer to improve efficiency of logistics and supply chain activities, and to enhance the entire supply chain management decision capacity. E-commerce has also become associated with solutions and

tools such as portals, e-marketplaces, e-auctions or virtual inventory. Logistics and supply chain operations have been affected irrevocably by e-commerce solutions. But the possible major changes could take a lot longer to happen. For companies, the overall goal of e-commerce includes (Yang, 2012): to help companies develop global sales network and logistics infrastructure which support efficient online order fulfillment; to provide enterprises with information and data of various business activities (i.e. online order documentation), production and sales information to solve the difficult problem of collection; to reduce market entry link that help companies open up the market to minimize the circulation of goods; to reduce business cost of sales and minimize the transaction costs of goods; both for trading and online commodity trading to facilitate negotiations; supports online purchasing including secure online payment system; to provide the most reliable quality assurance; to provide customers the most convenient means for retrieval. Supply Chain Management (SCM) is based on customer demand, providing a common focus on the related products or services, enterprise information resources, software products based on Internet technology as a tool to manage, the entire channel which all relevant processes to maximize net value added, and improve the efficiency and effectiveness of a platform. In this chapter, the evolution of logistics and supply chain and trends of e-commerce in logistics and supply chains are described. Then the discussion on the integrated e-commerce and e-commerce logistics are given and finally, it ends with future research directions and conclusion.

DOI: 10.4018/978-1-5225-2255-3.ch466

BACKGROUND

The rapid growth of e-commerce is being related to economic development and often been cited as a driver of economic growth. E-commerce is also touted as a powerful medium through which developing economies can exploit the potential of global markets. Today, e-commerce in developed economies represents the latest leader of change in physical distribution network and SCM, whereas in developing economies, e-commerce market is still in its infancy but it is expanding and becoming integral part of commercial life. This field evolved substantially over the past four decades and continues to grow today. In the early days, low prices and convenience were the driving forces for e-commerce, but today, e-commerce retailers (also known as e-tailers) are catering to

every kind of shopping experience, service and product. Presently, it remains the case that as the gross revenue earned from e-commerce is increasing year on year from nascence to critical mass, most transport service providers (TSP) or retailers, particularly multi- and omni-channel retailers, are only starting to realize what this will bring to their retail logistics and physical distribution network infrastructures and what role they can have within. So much as, today e-commerce has become a complementary retail touch point for the traditional brick-and-mortar retail.

The new e-commerce technologies have the potential to offer greater efficiencies and transparency and have led to significant changes within supply chains, with alternative ways of doing business, improved visibility and changes to distribution channels, including new interme-

Figure 1. The evolution of logistics and supply chain

diaries. From a distribution property perspective, the evolution of logistics and supply chain has passed through various phases and very broadly in the timeline as follows (JLL, 2013) (see Figure 1): most retail stores were replenished by direct deliveries from wholesalers and suppliers in the 1970s. The distribution centers (DC) emerged and retailers started to centralize store deliveries through new DCs that they controlled in the 1980s. Global sourcing took off in the 1990s, with many retailers developing import centers to receive and process mostly containerized imports. From around 2000, e-commerce began to rapidly expand with Internet-only (pure-play) retailers leading the way in establishing giant e-fulfillment distribution networks. In 2000, the business concepts like information sharing driving the extensive and intensive cooperation, collaborative warehousing, collaborative urban (city) as well as non-urban distribution are merged and implemented in logistics and supply chain operations (Capgemini, 2008). According to a study in developed economies the growth of online retail has been stronger in sectors such as fashion, electrical and ICT goods (Robinson, 2014). In the past times and models, there weren't many carrier options and purchased items were often distributed via a parcel, postal or freight network. However, e-commerce logistics models have created new demands.

There are four distinct types of logistics functions being setup (Robinson, 2014): An *e-fulfillment* center is a warehouse at which goods are stocked and chosen at item level. Today, there are numerous e-fulfillment centers, which are operated either by a retailer or a TSP such as eKart for Flipkart, JaVAS for Jabong and ATS for Amazon etc., often operating 24/7. Key facility configuration includes size (also called as big-box space which ranges from 50,000 to more than 100,000 m²) as well as features that contribute to more efficient picking, order fulfillment and throughput, such as accessibility for delivery vans, access to a strong employee base and cross-dock configuration. A *parcel hub/consolidation* center is where orders are sorted

according to geographical location, often by post or zip code, so they can be delivered to the relevant *parcel delivery* center for final delivery to the customer's home or designated collection point. Parcel delivery center handles the last mile delivery to the customer. *Seamlessly integrated technology* is where shopping carts connect via WEBXML, API or some other connection to a TMS, so customers get the exact price quote of shipping of larger items. Quotes are often more suited for less than truckload, as these technology products for logistics, such as a TMS, must accomplish along with the shopping cart for better management. These technology products for logistics feature: the ability to organize and track shipment according to transport modes; online order documentation and status; online dispatch invoice and documentation such as freight bills of lading and invoices; auto reminder for payments; seamless interface with existing ERP or SCM system; online alerts for critical information via mobile or text, information systems reports on delivery history, past data analysis, etc. Types of e-commerce logistics systems based on these considerations ensure the following benefits to transport users (e.g., shippers, receivers) and TSPs (e.g., carriers): improved communication, transparency into the supply chain, improved customer satisfaction, distribution and logistics optimization, cost reduction, improvement in efficiency and on-time delivery.

As online retail grows further, delivering order to customers quicker will become an increasing competitive advantage. As a result, the logistic facilities will encourage some retailers to set up their own networks of local depots - either to cross-dock items shipped from larger e-fulfillment centers or to ship certain fast moving products direct to customers. In this emerging model, e-fulfillment blends with urban logistics, as these facilities will be mainly based around the major population centers where online sales densities are highest. For example, in the U.S., Amazon opened smaller scale distribution facilities to offer same-day delivery services.

TRENDS OF E-COMMERCE IN LOGISTICS AND SUPPLY CHAINS

The e-commerce context is changing at a steady rate in both B2B and B2C, although it only represents 10% of all new leasing around the world, this percentage has doubled during the past three years, therefore companies have to anticipate strategies to manage these changes in their favor. Recognizing online presence as one of the biggest opportunity to expand and grow, many physical retailers have started to establish and increase their online presence. An e-commerce platform not only facilitates a transaction over the web, but it supports the creation and continuing development of an online relationship. The emerging trends of enabling e-commerce systems have been subject of discussion in recent years.

- **Cloud Computing:** There are four basic service configurations which are Software-as-a-Service (SaaS), Platform-as-a-Service (PaaS), Infrastructure-as-a-Service (IaaS) and Supply Chain-as-a-Service (SCaaS). In SaaS, the cloud user is able to access a software application hosted by an external provider over the Internet. Such as Google Apps, Salesforce. PaaS model describes a virtual platform which involves the use of an externally provided infrastructure to host the application like Apprenda, Google App Engine. IaaS provides virtualized computing resources over the Internet such as Amazon Web Services, Cisco Metapod, Google Compute Engine. SCaaS describes a framework for service oriented SCM such as OpenPMF SCaaS, HCL SCaS.
- **Mobile Applications:** Customer shopping habits have changed driven in part by increased use of mobile devices. Continued growth in tablets, smartphones, handheld devices use boosts the amount of time customers spend online – and they're more likely to shop there. With the proliferation of the Internet into daily life and the falling

data prices, customers access mobile applications conveniently to shop from any location like at airports, traffic signals, cafes or waiting in the line. This ease of ordering through mobile has further fueled impulse purchases. Companies are investing more resources for optimization of their mobile sites to enable customers to have seamless shopping experience across platforms.

- **Personalization for Customer Engagement:** Personalizing customer experience is a key customer engagement tool and is expected to drive e-commerce growth. With increase trend towards online shopping, brands are becoming more sophisticated in their ability to collect information about customers and using this data to deliver personalize recommendations, tailored offers and delivering differentiated experiences each time.
- **Big Data:** The Big Data has arguably been generated primarily from web and e-commerce communities. Significant market transformations have been accomplished by leading e-commerce vendors such as Amazon and Ebay through innovative and highly scalable e-commerce platforms and product recommender systems. Major internet companies such as Google, Amazon and Facebook continue to lead the development of web analytics, cloud computing and social media platforms.
- **Social Networks:** Social media has shown to be an effective platform for customers to discuss and voice opinions about products and brands, as well as for business to communicate with customers (DHL, 2015). Social media plays an important role. There are four different segments where marketing channels fit along the customer path to purchase: awareness, consideration, intent, and decision. Despite not being a direct sales channel, social media can support e-commerce logistics and supply chains in the ways (O'Leary, 2012):

Figure 2. Paradigm change in e-commerce

Demand information: using the percentage of likes and dislikes from social media exchanges as a measure of interest of customers in a product, thus providing some potential insight into customer demand. *Supplier choice:* Data mining of media such as Linked-In can provide important data to help infer information about whether a company will continue in business. *Logistics:* Information gathered over time about particular highways can help develop a better understanding of likely highway conditions. Effectively, intuition can be generated about routes and the likelihood of problems being encountered when moving goods over those routes

INTEGRATED E-COMMERCE

The evolution of multiple shipping options allows retailers today more control over their e-commerce logistics and supply chains. Today's customers have the ability to purchase whatever, whenever, however, wherever and at the price they want, putting them in total control of the market. With social media, mobile and e-commerce on the rise, omni-channel fulfillment is becoming increasingly important for retailers. Companies

in B2B and B2C commerce must be flexible and as omni-present as possible in order to remain competitive in this shop-anytime-anywhere world. As seen today, this trend is starting to displace the traditional role of parcel operators. Now the e-commerce challenge has shifting to finding a way of synchronizing and standardizing the business processes to achieve real time access and insight of the inventory movement. As predicted, retailers in developed markets are experiencing to shift from multi-channel retail to omni-channel retail. Paradigm change in e-commerce is depicted in Figure 2. Omni-channel retailers are managing their channels in an integrated way that offers customers a seamless experience, however they choose to shop. With omni-channel, a retailer may fulfill orders from local stores rather than warehouses, ultimately blurring the distinction between the two e-fulfillment centers.

With extensive number of sales channels, multiple warehouses, and dozens of suppliers, the risk of misplaced orders is much higher than ever before. In order to respond to this challenge, order fulfillment technologies have also helped integrate the front-end and back-end of online retail. Automated software and real-time fulfillment data transform the back-end process now in a collaborative effort. The alignment of important touch-points in the supply chain has

reduced inefficiencies and has helped identify redundant processes. There are even robots that pick inventory and move it around the warehouse (Robinson, 2014).

- **Multi-Channel:** Customers interact with retailers across the independently managed channels (e.g. social media, web and emails). Retailers with this approach are adopting two or more channels to engage their customers, however, they are not necessarily focused on delivering a seamless/consistent message across multiple touchpoint. Furthermore, these programs do not necessarily factor in optimizing customer experience based on different devices (e.g. smartphones, tablets and laptops).
- **Omni-Channel:** This business is diligent to ensure that customers receive the same experience and message through different channels and devices involved within their interactions with the retailer (Kourimsky & van den Berk, 2014). Thus, omni-channel has seamless integration with company software systems like ERP, WMS, warehouse control system, distributed order management (Hobkirk, 2016). Typically, omni-channel customers require their orders to be delivered within either same day or next day to their location of choice, whether the order is distributed to their home or can be picked up in a store or another location, moreover this type of customers expect to be informed of every step and any delays which may occur along the delivery process. Similarly, retailers have a holistic view into inventory in omni-channel environment, allowing them to fulfill orders from any location or ship inventory to other locations where inventory is needed or sells better. Omni-channel DCs share a common inventory pool and seamlessly combine both e-commerce and traditional store distribution channels in order to meet demand regardless of which

channel it comes from, whether customers are shopping online from a desktop or mobile device, by telephone or offline in a brick and mortar store. Basically, the goal of omni-channel is to give retailers an end-to-end view based on aggregated information from suppliers to customers, orders, and inventory.

In the past, retailers built two types of DCs, one to manage store fulfillment, whereas another to manage purely e-commerce. Omni-channel DCs seamlessly combine both e-commerce and traditional store distribution channels, omni-channel fulfillment strategies must be done right and quickly. Omni-channel improves the customer service through real-time integration with POS, web storefront and call center solutions, furthermore it increases flexibility and reduced costs through common carrier, small package and private/dedicated fleet delivery planning and optimization. It improves delivery control through transport execution capabilities including tendering, multi-carrier parcel manifesting, fleet dispatching, routing, proof of delivery and freight auditing, additionally transport operations are streamlined through carrier connectivity and global logistics network. To meet the challenges, retailers must completely redesign their distribution processes and add automation equipment to their DCs. In order to support the fulfillment promise, shippers must have technology and infrastructure in place to ensure sufficient response time between when customer places an order and when fulfillment center dispatches it. Additionally, significant capital investment is required in material handling, conveyor sortation and controls, optimized racking systems and lift equipment, inventory management software, and picking/packing technology.

E-COMMERCE LOGISTICS

In the context of logistics, e-commerce platforms can be termed e-commerce logistics platforms.

Figure 3. Overview of e-commerce logistics platform with consortia partners

E-commerce logistics is the use of web-based technologies to support the material acquisition, warehousing, and transportation processes. It enables distribution to couple routing optimization with inventory-tracking information. This platform is an inter-organizational system (IOS) that links transport users and TSPs together for the purpose of collaboration or trading. It enables online interactive transport exchanges in terms of transport supply and transport demand in order to match freight capacity with available shipments (Christiaanse, 2005; Kale et al., 2007; Wang et al., 2007). For example, internet-based freight acquisitions enable spot buying of trucking capacity. TSPs offer virtual logistics services by integrating and optimizing distribution resources. A company may even consider collaboration with its competitors to improve its supply chain. Utilizing the web has largely reduced the complexity and cost of implementation and the integration of IOSs. Incorporating the concept of cloud computing services, e-commerce platforms are emerging quickly as a viable alternative to large-scale client-server solutions (Kayikci & Zsifkovits, 2013; Wang et al., 2007), especially where they are hosted by the technology provider. Traditionally, transport software programs (e.g., TimoCom, TransMATCH) are developed for specific platforms, such as Windows, Linux, or Mac OS, where parties are advertising freights (cargoes) and looking for empty trucks. Today,

platform developers build web-based (e.g., www.timocom.com) as well as mobile-based (e.g., TimoCom transportbarometer) applications, as communication tool in supply chain that run on Internet and on mobile, that are completely independent of the user's actual computer operating system. E-commerce platforms offer powerful online solutions for transport collaboration, where TSPs easily search online for freight or post any spare capacity in order to increase load factor for return trip. Similarly, transport users offer freight for transportation or search for suitable vehicles.

Today companies (e.g. Shipwire) access end-to-end orchestration and fulfillment capabilities on web-based enterprise fulfillment platforms (DHL, 2015). These make it easy to access specific services and grow into new markets. Customers can choose their preferred transport option and this is factored into the total cost of the product (e.g. FreightOS). E-commerce logistics platforms offer three different types of business activities (Kaplan & Sawhney, 2000):

- *Aggregators* create a business community where TSPs offer freight capacities with predefined prices (e-catalog) for transport users on a website (e.g., Freefreight search).
- *Auctions* create market and reduce empty trip and promote the load factor, where transport users can bid simultaneously

for the TSP's freight capacity according to multiple real-time auction systems (e.g., FReight Exchange for International Transport-ONlinE).

- *Exchanges* create stable online market, where selected transport users and TSPs trade freight according to a fixed set of rules and at constantly changing prices (e.g., Transplace); this Expedia-like platform for freight providing instant, online real-time quoting for all legs of shipment. Shippers can generate and book instant, door-to-door quotes directly online, using their own internal negotiated rates or rates shared online by carriers or forwarders.

Characteristics of an E-Commerce Logistics Platform

- **Platform Community:** The network for transport exchanges allows transport users and TSPs to create *communities* to better manage their transport needs and resources (Kayikci & Zsifkovits, 2013). Figure 3 depicts an overview of e-commerce logistics platform with various consortia partners. If a transport coalition is composed of pre-selected members on *vertical plane*, it is called then *private community*; most of the time this community is closed and specific requirements should be fulfilled to enter into this community. If a transport coalition is composed of only receivers, then it is called *receivers' community* where the platform primarily serves interest of receivers; likewise, if it is composed of only shippers, which is called *shippers' community* and the platform serves the interest of shippers; if only carriers are collaborate, then it is *carriers' community* where the platform primarily serves interest of carriers. If shippers, receivers and carriers integrate together on the *lateral plane*, it is denoted as a *neutral community* which has generally heterarchical structure and serves interest of all participants and is often managed by a group of consortium. That means, there is no dominant community which rules the coalition, therefore

an independent platform usually tries to be of direct use for shippers, receivers and carriers. *Neutral community*, where the aforementioned three communities collaborate each other and their communications are supported by a neutral technology provider which is called as control unit (CU). This community is characterized by a high level of transport collaboration. It is web-based and hosted platform and enables high level information sharing and joint activities.

- **Platform Strategy:** E-commerce platforms are divided into two types: open and closed platforms. *Open platform* allows transport parties to use their services with no barriers to entry whereas *closed platform* tends to be geared towards the needs of particular shippers, receiver and carriers (Wang et. al, 2007). Closed platform denotes private community in other words, semi-private or private networks where the all participants know each other and they share information on shipping requirements. Most of the transport users prefer to collaborate in a private network rather than in an open network, however close platforms are less structured and often contain the opinion of large companies (Chen et al. 2012), whereas open platforms acquire bigger negotiation capability and offer more freight matching opportunities than closed platforms. However, the open platforms are not suitable in high level of transport collaboration (Cruijssen et al., 2007; Wang et. al, 2007). Especially strategic partnering level requires closed platform strategy.
- **Platform Sourcing:** The platforms also differ in how total freight load capacity is bought. Generally, transport users either engage in *systematic sourcing* or in *spot sourcing* (Kaplan & Sawhney, 2000). First, transport users can acquire freight capacity in a truck through fixed-commitment contracts and negotiated market prices

with TSPs. Especially major shippers and forwarders use *systematic sourcing* for acquiring available freight capacity (Kayikci et al., 2014). The *closed private platforms* exemplify this approach. Second, in *spot sourcing*, transport user's goal is to fulfill an immediate need at the lowest possible cost, whereas TSP's goal is to utilize truck space at the highest possible profitability. The *open source auction platforms* elucidate this approach. Spot transactions are being accompanied by development of a short-term, loose relationship among transport users and TSPs.

- **Platform Capability:** Development of an online platform includes creation and management of an online storefront, shopping cart management, PCI compliance, personalization transaction management, settlement and product visualization – enable organizations to build basic B2B or B2C online stores. Some specific capabilities in electronic communications are determined (Hajdul, 2014) that are essential for e-commerce platforms with the collaboration of transport users and TSPs: web-interfaces, event management / alerting functionality based on (re-)calculated routes/plans, reporting, transport/purchase order management at company level, monitoring of the performed task, digital map, route optimization, invoicing, fleet management, freight exchange, real-time monitoring of the performed tasks, transport/purchase order management at group of independent companies level, verification of business partners, coordination of transport orders and resources of independent companies, optimization of truck loading process, share of savings among group of cooperating companies, load tracking, deliveries, support of existing communication standards, settlement and reports. E-commerce

platforms can also include personalization/preference profiling, multichannel selling, site/product search, search engine optimization, customer community management or participation, integration with social media, and mobile stores.

FUTURE RESEARCH DIRECTIONS

Customer buying behavior is evolving faster than logistics and supply chains can adapt. The rapidly changing delivery expectations of e-commerce customers, driven by trends towards click & collect and next day delivery, mean that operating an effective e-commerce supply chain and fulfilment operation presents a whole new set of challenges. To meet these new expectations, e-tailers need to find new solutions at every stage, from demand forecasting, through to inventory management, warehousing, technology integration and distribution. A strong mobile presence, in-stock merchandise, and fast delivery are important keys to e-commerce success, and a strong argument for top-notch logistics solutions. Today, supply chains are segmented by channels, which results in duplication of inventory and infrastructure. Only few companies (such as Vargo) are beginning to offer omni-channel DCs, so that separate channel spaces within the same warehouse and different automation solutions are used in order to easily respond the changing supply chain demands of B2B and B2C channels. Unfortunately, there is still limited research associated with how e-commerce in terms of new trends has been and can be used in the logistics and supply chains. From this perspective, many opportunities for future research might be opening for researchers. These new research areas might be big data analytics in logistics and SCM, adapting industry 4.0 in logistics and supply chain, setting the strategies for omni-channel logistics, omni-channel integration as well as designing omni-channel DCs.

CONCLUSION

Expanding ICT has broken down barriers to make it easier to start and grow a business online in every industry and logistics and SCM continue to be pushed in new direction by e-commerce. The new trends in e-commerce like cloud computing, mobile applications, big data, social networks can offer great opportunities for companies in order to redefine their corporate strategies and to redesign their business models. The percentage of e-commerce sales is growing continuously and the increased volumes are putting unprecedented demands on the supply chains of e-commerce and omni-channel retailers. In this chapter, a broad overview of current e-commerce applications in logistics and SCM is given. It gives researchers and practitioners better understanding the role of e-commerce in logistics and SCM in order to expand business and provide competitive advantages.

KEY TERMS AND DEFINITIONS

E-Commerce: E-commerce refers to conducting business communication and transactions over networks and through computer technology or buying and selling goods and services (also known as e-business), and transferring funds through digital communications.

E-Tailer: An e-tailer is a retailer that primarily uses the Internet as a medium for customers to shop for goods and/or services provided.

Omni-Channel: Omni-channel involves providing a seamless, consistent and complementary customer shopping experience across all interaction channels like in store, on the web, and on mobile devices.

Exploring Drivers of Closed Loop Supply Chain in Malaysian Automotive Industry

Fadzlina Mohd Fadzil

Universiti Sains Malaysia, Malaysia

Yudi Fernando

Universiti Malaysia Pahang, Malaysia

INTRODUCTION

With the emergence of industry, people have become voracious pursuit of profit, in which they affect the environment and social wellness. Issues related to environmental and social destruction such as pollution, carbon footprint, ozone depletion, deforestation and waste management problem had threatened the environment and human being on this day. These environmental issues have caused resurgence and challenges in finding a solution to this problem, namely sustainability.

The concept of sustainability has been introduced by the World Commission on Environment and Development (1987), has given a change to the business world today. The issue of sustainability has brought changes to the terms of a business venture of the company's goals, operations, manufacturing, supply chain, administration and marketing. The concept of sustainability has rejuvenated the world of supply chain where green practices in supply chain can reduce environmental impacts. The green supply chain management is defined as the integrated supply chain management where it revolves around the green purchasing ranging from suppliers, manufacturers, users, and so the process will revert to reverse logistics, which will close the loop process of the supply chain (Q Zhu et al., 2005).

BACKGROUND

This study takes the approach of a closed supply chain in the automotive industry in Malaysia. automotive industrial sector in Malaysia has been developing since Malaysia has its own national car industry and is seen as encouraging growth in the national economy to this day. Starting in 2015, the Malaysian government has imposed regulations to the automotive industry to perform activities 3Rs reduce, reuse and recycle. This has made the automotive supply chain to the supply chain is closed. Therefore, this study examined the main factors that make the automotive industry players to engage in the closed loop supply chain.

CLOSED LOOP SUPPLY CHAIN

Closed-loop supply chain is defined by Guide & Van Wassenhove (2009), as a supply chain management which can maximize the creation of value through the entire life cycle of a product and also the dynamics of the recovery of the species and the number of returns in a short period of time. The maximizing value creation process and also the dynamics of the recovery is obtained through the design, control and operation of the system.

The closed loop supply chain combines both forward and reverse supply chain where these green

practices able to minimize the industrial waste and also reduce the environmental impact. The practice of zero-waste which includes recycling, reuse, reduce, remanufacturing, refurbish and repair in closed loop supply chain has generate a process of cradle-to-cradle where it can generate values not only in terms of profitable values to the shareholder and also to its stakeholders. Shaharudin, Govindan, Zailani, & Tan (2015) stated that when the organization could identify the benefits of all types of product returns, then the combination of design for forward and reverse supply channels and an environmentally friendly way to dispose the product; it will then give the organization the ability to achieve sustainability in business.

Forward Supply Chain, Reverse Supply Chain and Reverse Logistics

Traditionally, supply chain management is revolving on the forward supply chain. For the forward supply chain, it starts from the raw materials purchases from the supplier to the manufacturer, manufacturing and assembling operations, distribution centre, then to the distributors and retailers, and ultimately to consumers (Souza, 2013). However, the traditional supply chain ignored the elements of environmental conservation and end of life of the product is considered as waste. As for the closed loop supply, it will change or renew the end-of-life phase of a product where the old product will be refurbished or remanufactured. Closed-loop supply chain will help in reducing the amount of industrial waste disposal of non-biodegradable and hazardous material and also reducing the shortage of landfill capacity for industrial materials disposal. Recently, the automotive industry starts to adopt this green practice in order to minimize the environmental impact. Among the product returns received in closed loop supply chain is the commercial returns, repair or warranty returns, leasing, end-of-use returns and end-of-life returns.

The reverse supply chain is established to manage the return of products from the consumer to the manufacturer and also from the manufacturer to the supplier (Schenkel, Krikke, Caniëls, & der Laan, 2015). According to Günther, Kannegiesser, & Autenrieb (2014), the process of closing the loop in the supply chain or reverse supply chain, it is including the important context of sustainable supply chain management; the reuse, refurbishment or recycling of goods. By closing the loop, it involves the final stages of life-cycle of a product where the product will go through processes of recycling, remanufacturing, reclamation and also reverse logistics (Sarkis, 2012).

In the closed loop supply chain system, the reverse supply chain will collect the product return from customers and returned to the original manufacturer in order for improvement and also enhances by refurbishment, remanufacturing, repair or recycle; either certain parts or whole parts of the product. This provided benefits for reverse supply chain and has been an emphasis on the manufacturing industry to shift towards convergence of the strategy to increase the product life cycle, in which they not only provide good value for but as well as integrated supply chain management strategies (Genovese, Acquaye, Figueroa, & Koh, 2015).

Closed loop supply chain could focus on product return and repair or improvement of products either by component or the entire product. Reverse logistics plays a key role in the implementation of closed-loop supply chain. The process of reverse logistics includes planning, implementing, controlling efficiency, cost effective flow of raw materials, the process of purchasing or inventory, finished goods as well as information related to the value or disposal of waste properly (Aravendan & Panneerselvam, 2014). The reverse logistics that have been effectively implemented could ensure the success of the implementation of closed-loop supply chain, in which they could reduce dumping in the inventory and distribution costs could be salvaged. The closed loop supply chain can

also increase the level of customer satisfaction as it recapture the economic value of the returned product, where the process of improvements, re-cycle, refurbishment or remanufacturing able to produce products at a lower cost (C. K. M. Lee & Lam, 2012). By adopting automotive closed loop supply chain management, the firms managed to reduce manufacturing costs of parts, reduce user costs, reduce carbon footprint released, reducing the rate of disposal of goods and pollution.

DRIVERS OF CLOSED LOOP SUPPLY CHAIN IN AUTOMOTIVE INDUSTRY

The closed loop supply chain management for Malaysian automotive industry requires drivers that could encourage more manufacturers and automotive suppliers to participate to adopt green supply chain and to ensure the success implementation of the closed loop supply chain so that it could address the problems associated with economic, environmental preservation and social development. The identified drivers closed loop supply chain could help in reducing the environmental impact and concerned on social benefits are listed below.

Customer Awareness

Customers nowadays conscious on the product benefits, services, value added products product effectiveness, cost and also conscious on environmental. Customers that have high awareness of the environmental issues will only buy products manufactured by firms that do green practices. High consumer awareness on the importance of protecting the environment could increase the level of participation of manufacturers and suppliers to do closed loop supply chain.

The closed-loop supply chain also covers business-to-customer and business-to-business customers such as the automotive manufacturer

and suppliers. Customers nowadays are not only focus on the price and quality of a product, but also sensitive to the choice of the products produced by manufacturers who are ethical and concerned on environmental issues. Therefore, if the manufacturer has a high awareness of environmental issues, the manufacturer will put a condition on the supplier to perform closed loop supply chain where product return undergoes recycled or re-manufacturing; so that the product is not directly disposed. This makes suppliers facing off with competition and also aware of the importance to practice green supply chain management. Awareness about sustainability is growing among consumers have been demanding automotive OEMs to do closed loop supply chain by recalling the defect products from their suppliers for new cycle or life of a product. (Go et al., 2011).

Akdoğan & Coşkun (2012), explains that in compliance with the law and also the creation of a responsible image in taking care of the environment, are the motivation behind the implication of closed loop supply chain. By practicing closed loop, it makes the firms has compliance with the law and this will make customer realize that the firm is really taking care on environment. This also could raise the level of awareness of the customer to return the product and get better options. Green supply chain practices will guarantee better quality service and also seen as a positive image of the company in addressing environmental issues.

The increase awareness on eco-friendly manufacturing solutions has made manufacturers including suppliers to establish green initiatives that are environmentally friendly. The industry players are urged to take a more green operation and green strategies in order to minimize negative impact on the environment (Xu et al., 2013). Evangelista (2014), stated that when customers have a high awareness of environmental issues, then it will help the organization to do green practices in achieving sustainability. This shows that high awareness of environmental preservation will increase the number of suppliers and

manufacturers to implement closed loop supply chain to do more recycling, remanufacturing or product improvements.

For manufacturers who have a high level of awareness about preserving the environment, they may educate their suppliers in matters related to the activities of environmental management. This will make the manufacturers and suppliers to have mutual understanding of the importance to preserve the environment and the wellness of society (Tarig K. Eltayeb, Zailani, & Ramayah, 2011). Through education on sustainability, suppliers will be aware of the importance of carrying out the green supply chain as an effort to minimize the impact on the environment. It could assess the level of awareness of the supplier of the products they produce, whether the product conducted in an environmentally manner and how goods will be dispose after the lifecycle reaches end. Suppliers can also understand the needs of customers who want quality products without adversely affect to the environment.

Governmental Legislation

As environmental issues have been a concern across the country, Malaysia also emphasized this issue mainly in terms of environmental protection and public wellness. In 1974, the environmental act has been established and this act has been amended several times include 18 sets of regulations related to clean air, waste and industrial assessment. The national environmental department stated that the manufacturing industry is a major contributor to pollution and destruction of natural resources. Therefore, it is important for Malaysia to achieve a balance between living standards and environmental protection (Zailani et al., 2015).

The awareness among stakeholders on the issues related to preservation of the environment has led to the establishments of environmental legislation and regulations in order to plan and design approaches that are appropriate to balance the development and conservation (Mondéjar-

Jiménez et al., 2015). Due to the increase in awareness of the importance of protecting the environment and also the implementation of the regulation by the government, then this has created conditions in which the parties involved in the industry and policy makers to look at the impact of supply chain activities on the environment (Fareeduddin et al., 2015).

Law plays an important role for the implementation of closed-loop supply chain. Starting in 2012, the government of Malaysia has ordered all party manufacturers and automotive suppliers to adopt a closed loop supply chain namely with 3Rs: Reduce, Reuse and Recycle practices in order to reduce the impact on the environment and also to reduce dumping in landfills. By imposing laws, acts and regulations relating to environmental preservation, then the parties involved in industries such as supplier and manufacturers could comply with regulations and this will force the parties to take green initiatives to mitigate the impact on the environment. The authorities will monitor and imposed penalty if there are any of those who violate the rules or performing their businesses unethically.

According to Eltayeb et al., (2011), in response to comply with the rules imposed by the government, including regulatory institutions, organizations are expected to take the approach through the purchase of green as additional adherence to the rules that have been imposed on them. In addition, the firm will also try to avoid potential excessive cost, any uncertainty and legal liability relating to environmental regulations. The regulatory institutions will monitor the activities of the operations carried out by the firm to ensure that every operation carried out does not affect the environment. Incentives are also offered to firms that comply with regulations. Even though in Malaysia there are no specific implementation rules relating to the nature of the industry which requires reverse logistics activities, but the government has begun to steer the organization to adopt green practices implemented by the automotive industry in western

countries. The government has offered incentives such as rebates and tax exemption to the firms that volunteered to do green practices.

Environmental Concern

The raising responsibility in preserving the environment has led companies began to realize the importance of performing green supply chain management. To ensure that sustainability can be achieved for a long time, the upstream and downstream is an important factor in playing a role in improving supply chain performance while satisfying customer needs (Ageron, Gunasekaran, & Spalanzani, 2012). This can be done by linking the channel of suppliers in the closed loop supply chain to collaborate in order to make the sustainable initiative in supply chain.

There are seven environmental requirements and economic aspects of sustainability practices stated by Diabat, Kannan, & Mathiyazhagan, (2014). The requirements are consisting of reduction in waste and emissions; reduction in energy intensity of goods and services; use of renewable and sustainable energy resources; maximum use and re-use of recycled components and materials; measurement and assessment of business impact on ecosystems; standard measures for evaluating sustainability performance; and environmental consciousness pervading the culture of an organization.

To address issues related to the environment and returns a profit, the firm needs a business model that is comprehensive and viable to develop strategies that effectively green supply chain (Das & Rao Posinasetti, 2015). Organizations that have a high awareness in environmental management could affect the participation of the supplier's also the success of green initiatives in the supply chain. Firms can make green initiatives as a corporate program and innovation from suppliers to ensure increased participation in achieving sustainability (Caniëls, Gehrsitz, & Semeijn, 2013). Therefore, many firms have realized the importance of working collaboratively with partner suppliers to

produce products that are environmentally friendly and can be recycled where it would improve their sustainability performance. In addition, the firm also create awareness, educate and convince consumers (Gopal & Thakkar, 2015).

The good and functioning conditions parts such as engines, transmissions, starter motors, alternators, water pumps, doors and bumpers could be reuse on other vehicles of the same model. Materials from batteries, catalytic converters, tyres and plastics are extracted and recycled into new products. Fluids such as engine oil, coolant, and gasoline are carefully collected and stored in double-walled tanks or secondary containment prior to being reused or recycled. Therefore, if the end of the life cycle of these components is only allowed for the disposal, then it will increase the rate of pollution. By perform closed-loop supply chain, the end life cycle of these components can converted into another new life cycle product.

Social Responsibilities

Traditional supply chain is more subjected to the economic perspective. However, the closed loop chain has revolved around the impact of industry on the environment and also social wellness. Social responsibility, ethical funds and eco-efficiency has shown that ongoing efforts to achieve sustainable social development (Diabat et al., 2014). The practice of social responsibility is regarded as important in which it is an effective solution to achieve such sustainability could help to deal with problems related to social development and environmental issues (Habidin et al., 2015).

The aspect of the closed loop supply chain is not only subject to cost, quality and financial performance. Issues of social development and preservation of the environment has attracted many parties such as customers, investors, regulators, government bodies and non-governmental organizations and the public to co-evaluate the importance of green supply chain management or closed loop supply chain. However, social issues are often neglected. Environmental issues such as

carbon emissions are more highly regarded while social impacts is ignored (Klassen & Vereecke, 2012). However, social issues, health and welfare of local residents should also take precedence over environmental issues. This is because by being concern on social issue, then the firm has provided assurance that the operations or activities carried out by them does not affect the welfare and health of future generations. This also educate the public that the current generation and future generations is equally important to achieve sustainability.

Waste Management

The traditional open supply chain focuses on player chain suppliers, manufacturers, distributors, retailers and end users. Usually the products will be disposed after its end of life. This increases the number of waste for disposal and reduce the value of the product. In the closed-loop supply chain, the product that has come to the end of life is could be converted from waste into other product. Therefore, it makes the cradle-to-grave business has turned to a cradle-to-cradle opportunity and makes the experience of the old product that undergoes improvement process could be reused.

The growth and industrial development in Malaysia has resulted in an increase in the production of industrial waste. The environmental management practices are very important aspect in a variety of industrial applications in all countries around the world. Efforts to reduce the disposal of waste in the manufacturing industry will improve environmental management. For the automotive industry, most automotive manufacturers have implemented environmental management to improve the operating performance of the company (Fadly Habidin et al., 2015).

Tarig Khidir Eltayeb & Zailani (2011), stated that a lot of efforts and expenses have been undertaken by the authorities in the management of solid waste disposal. The raising awareness of protecting the environment in many countries

have led the efforts to recycle and convert end of life products to new products. In Malaysia, the approach to end-of-life of a product will mostly end up in landfills or through the combustion process. This will result in damage to the land drainage and also carbon and other harmful gas emissions. Through the implementation of National Automotive Policy in 2014, all the suppliers and manufacturers are instructed to take green initiatives such as 3R. Therefore, the implementation of the closed-loop supply chain activities is able to reduce waste from industry.

Therefore, by performing closed-loop supply chain so it could help reduce the problems associated with landfill and also reduce the level of carbon emissions. Returned product will undergo a process of recycling, remanufacturing or improvements in production which could be produce at a lower cost. This would bring benefits for firms and consumers. Thus, the automotive industry in Malaysia could do refurbishment or repair of car components, engines, internal and external parts or electronic parts from product returns and it could be sold to the consumers at lower price. This green initiative will reduce the dumping of car components that have reached the final life cycle stages in the landfill.

FUTURE RESEARCH DIRECTIONS

There are many areas of closed-loop supply chain in the automotive industry to be explore. The closed loop supply chain for automotive industry in Malaysia is an emerging trend and have a promising future. For research related to closed loop supply chain in the automotive, it is suggested that researchers to study the effectiveness of drivers in influencing suppliers and manufacturers to perform closed-loop supply chain. With this, the performance of closed-loop supply chain could be evaluated.

CONCLUSION

This study focuses on the management of closed-loop supply chain and identify the drivers that can drive closed-loop the supply chain management for the Malaysian automotive industry. The implementation of a closed the supply chain management for the automotive industry in Malaysia is expected to help the country and also the automotive sector to achieve sustainability. In addition, it also could reduce the environmental issues that related to the automotive supply chain. The consumer awareness is essential for carrying out the closed loop supply chain, where it affects the market demand. The implementation of laws or regulations will ensure that the suppliers as well as manufacturers to comply with the rules relating to the use and disposal of products is carried out according to proper procedures, to ensure the well-being of nature and community is maintained. The organizations that are aware of the importance of protecting the environment shows that the organization is no longer focused on profit alone, even green initiatives and practices could reduce the environmental impact. Through environmental awareness, the organization will be more socially responsible, where the global community health and welfare are not jeopardized. While, waste management is the organization which manages the industrial waste in a way that is more environmentally friendly. Drivers described in this study were identified to be the catalyst for the automotive industry in Malaysia in promoting the growth of the automotive closed loop supply chain, contributing to excellence in the automotive supply chain as well as the achievement for a better sustainability.

KEY TERMS AND DEFINITIONS

Automotive Original Equipment Manufacturers: Automotive original equipment manufacturers (OEMs) assemble single components to final vehicles that are sold via a dealer-network to business and private customers.

Closed Loop Supply Chain Management: Closed loop supply chain management is the design, control and operation of a system to maximize value creation over the entire life cycle of a product with dynamic recovery of value from different types and volumes of returns over time (V. D. R. J. Guide, Harrison, & Wassenhove, 2003).

Green Supply Chain Management: Green supply chain management or GSCM has emerged as an important new archetype for enterprises to achieve profit and market share objectives by lowering their environmental risks and impacts and while raising their ecological efficiency (Qinghua Zhu, Sarkis, & Lai, 2008).

Reverse Logistics: Reverse logistics are the process of planning, implementing, and controlling the efficient, cost effective flow of raw materials, in-process inventory, finished goods and related information from the point of consumption to the point of origin for the purpose of recapturing value or proper disposal (Govindan, Soleimani, & Kannan, 2014).

Supply Chain Activities: Supply chain activities is a set of activities that includes purchasing, manufacturing, logistics, distribution, marketing, that perform the function of delivering value to end customer (Paksoy, Bektaş, & Özceylan, 2011).

Supply Chain Management: Supply chain management is the integration of key business processes from end users through suppliers that provides product, services and information that add value for customers and stakeholders (S. M. Lee, Tae Kim, Choi, Kim, & Choi, 2012).

Sustainable Development: Sustainable development is the development that meets the

needs the present without compromising ability of future generations to meet their own needs (WCED, 1987b).

Value Creation: The creation of value is the core purpose and central process of economic exchange. Traditional models of value creation focus on the firm's output and price. Value is created by the firm in the form of a good, and this valuable good is exchanged in the marketplace for money (or possibly other goods). Value creation refers to traditional supply chain objectives, customer satisfaction and cost reduction, as well as environmental goals (Schenkel et al., 2015).

From Business-to-Business Software Startup to SAP's Acquisition

INTRODUCTION

Nearly one trillion in commerce was contributed by more than two million buyers and sellers around the world last year. Organizations tapped into the comprehensive source-to-pay solutions and business network offered by SAP Ariba. They digitized their supply chains and efficiently managed their trading relationships (SAP Ariba, 2016).

Ariba, Inc. was born during the dot-com bubble, at that time a start-up with great potential along with countless other e-commerce companies. The shake-out that occurred later on among a plethora of competing businesses, confirmed the solidity of Ariba's focus and business model while competitors like Commerce One, could not stay in business. However, the interesting evolution of Ariba, from a pioneer to a sufferer to a survivor, has taught us much about survival in the competitive business to business (B2B) software industry. Ariba's software would help many companies save money on their procurements, and control expenses in numerous areas aside from payroll. Ariba promised to help companies improve their bottom line, and many of Ariba's clients today hold positions on the coveted Fortune 100 list. Going public in 1999, Ariba's stock price at one time reached \$259 per share. At the time, Ariba was still getting their feet wet; they had not yet made a profit. In 2000 their stock reached \$168.75, but a negative turn in the economy lay just ahead. Many companies

began to cut back on investments and in just 9 months Ariba lost 95% of its value. This would be disastrous to any company, and would be the downfall of most, but Ariba made some critical key decisions that helped continue its leadership in the B2B e-commerce world (Clarke & Pucihar, 2013; Schumann et al., 2014). They are one of the few companies to not only survive the burst of the dot-com bubble, and but to thrive, and to this day remains a successful company. Ariba was purchased by the German software firm SAP for \$4.3 billion in 2012 (Jones, 2012).

BACKGROUND

E-commerce was in many ways revolutionized by Ariba Inc., a leading independent company in the sphere of B2B commerce network providers. Since the time of its founding, the company has been evolving constantly, in cooperation with leading companies in the industry, in order to deliver e-commerce platform products to its customers/clients. Its value chain model was successful in helping it to develop business relationships further than expected, the results of which made it a top 40 Fortune 500 company.

Ariba has overcome many obstacles, including lawsuits, changing customer requirements, and organizational restructuring, however still managed to remain a leader in its specific niche

DOI: 10.4018/978-1-5225-2255-3.ch468

industry area. The firm has done so by delivering solutions and services that meet customers' expectations, and have been able to cope with intense competition by keeping up with today's technologies as well as developing solutions for tomorrow. Ariba was founded in Sunnyvale CA, in September 1996, by seven men, one of the most influential being Steven Krach. Krach's early career accomplishments included being one of the youngest vice presidents of General Motors (Ariba, 2008). The challenges of procurement that he encountered there became the impetus for the development of Ariba. Through the use of the Internet and B2B e-commerce, Krach and his associates brainstormed and came up with the idea of automating the purchasing of commonly used supplies and services. While this may seem to be a rather simple concept, it turned out to be an insight and area that held huge demand and potential.

After three months of intensive research, which included meeting with 60 Fortune 500 companies, Ariba had a prototype developed and ready for their initial marketing campaign. Having signed software licensing deals with Cisco Systems, Advanced Micro Devices and Octel Communications, prior to software completion, the pieces were put into place for the launch of their product. While Krach and Ariba were innovative in their concepts and efforts, they were not the only pioneers in the area, Commerce One, Oracle, I2, and PeopleSoft, Inc. were competitors with similar, but not necessarily identical, offerings.

The objective was to become a leader in this niche industry with the means and resources to provide procurement software and network consulting services, which would allow corporations to manage and automate their spending more effectively and efficiently. The management of these would include essentially all non-payroll expenses associated with running a business. Since access to data was one critical component, Ariba offered their clients real-time access over the Internet. These applications were used in conjunction with the *Ariba Supplier Network*

to purchase goods and services. Ariba is a firm that is customer driven, and as such offered full support, including technical support, implementation, training, and consulting programs and packages. E-payment and service agreements were made with American Express and Bank of America. All of these were considered large and bold undertakings for a young startup company at that time. In June of 1999, Ariba went public at a modest \$23 per share, however traded as high as \$259 per share at times later that year (Schneider and Bruton, 2008; Haksoz and Seshadri, 2007). This was a phenomenal success for a three year old company which had yet to turn a profit at that time, since it benefited from being a "first mover" in the business. However, as mentioned earlier, other Internet start-up companies were beginning to offer similar software and services. Over time, smaller companies began offering websites that provided a place to manage procurement, some with lower costs and fees. Facing challenges in the market, Ariba was to be faced with difficult challenges and had to make major decisions in order to stay in business.

Ariba finally saw a profit of \$10 million in December of 2000, which also included the completion of a few *acquisitions*. Soon after, in 2001, the economy began to weaken in a downward spiral and Ariba's stock plummeted 95%, making a business overhaul necessary. Ariba decided to take drastic cost-cutting measures, cutting about a third of their staff. Because of their specialized and niche product line, their business was able to continue and survive the setbacks faced by other Internet software companies. Krach resigned as CEO in 2001, but stayed on as Chairman and appointed a CEO that would later cost the company much money and negative publicity. The bursting of the dot-com "bubble" marked the beginning of a relatively mild yet rather lengthy early 2000s recession (Marshall, 2001; Sahay, 2007). In time, Ariba, along with the rest of the B2B business community ran into two big problems. First, the brick-and-mortar Old Economy was stable and could adjust more readily to economic

downturns. Second, companies were interested in saving transaction fees by using alternate means instead of using costly B2B networks (Cerquides, López-Sánchez, Reyes-Moro, & Rodríguez-Aguilar, 2007).

Overtime, however, Ariba persisted and would once again regain its position as a leader in the B2B procurement industry. The firm made adjustments where necessary to continue to deliver the goods to their clients, without sacrificing their own bottom line. According to the current CEO, Bob Calderoni, Ariba is well positioned in the spend management market and will continue to grow in the current tough global economy.

The following sections explore the internal (*adaptations to a competitive environment, acquire to advance, consulting adds value, emphasis on the customer*) and external (*severe competition, high-priced software, regulator's investigation, unhappy customers*) factors that affect the company's struggles and challenges.

INTERNAL FACTORS

Adaptations to a Competitive Environment

At the height of the e-procurement frenzy, two companies dominated the B2B space: Commerce One and Ariba. Due to the near-collapse of the original B2B procurement model, both companies sought new niches. Commerce One moved towards web services in an attempt to seek viable markets. Ariba, meanwhile, emphasized enterprise spending management (Kinsey, 2004). Ariba strongly believed that a software firm's role first and foremost is to be a software tool provider. As the B2B world divided into industry sponsored exchanges and independent marketplaces, Ariba avoided making inroads into involvement in managing its customers' exchanges. In contrast to this, Commerce One believed that software makers had to do more than simply provide software tools. They believe the right approach was to form strategic

partnerships with its customers and to help manage their online marketplaces (Anderson, Opie, & Watton, 2003; Bannan, 2008). It also directed its customers towards an international trading network in order to build critical mass and facilitate e-commerce between them.

As a new CEO, Calderoni monitored the external environment, where a fundamental shift in the marketplace existed, and responded promptly to adjust the company's product offering. He believed that B2B e-business had a direct and indirect impact on all functional areas, and that these linkages with a company's supply chain system were critical. In effect, Ariba was changing its focus from e-procurement, to offering products that can increase customer satisfaction by solving a variety of "spend-related" problems faced by corporations (Tadeschi, 2008).

With the concept of division of labor as a microeconomic view, Calderoni added a purchasing system, general ledger, and field system into Ariba's line of products. The added features in the company's products were favored by Ariba's existing customers in the automotive, chemical, and manufacturing industries due to the ease of system comparability. The need to transfer data from legacy systems enabled these customers to remove outdated and inaccurate data from their systems and which also helped to improve relationships with their customers.

Acquire to Advance

According to Krach, a major component of Ariba's business model is partnering followed by organic growth and acquisition, and so the firm continued to follow this basic approach to help ensure the firm's success. Ariba acquired companies that had the technology and resources they needed to survive, instead of taking the time to develop them in-house. Mr. Calderoni implemented an aggressive acquisition strategy that significantly expanded Ariba's technology offerings and service capabilities, and positioned the company as a recognized leader in its market. One goal was

to secure top Fortune 10 companies and Global 500 companies as customers (Efendi et al., 2013).

In 2004, Ariba acquired Alliente Inc. and FreeMarkets Inc. to link their spend management software with its existing capacities as a B2B procurement hub. The acquisition of FreeMarkets increased Ariba's offerings by providing global supply management software and services. This acquisition also positioned Ariba as a serious contender in the automotive industry, adding General Motors Corp., Daimler-Chrysler AG and Ford Motor Co. to their customer base. By acquiring Alliente, Ariba expanded its spend management and procurement capabilities to include a procurement out-sourcing provider (Hosford, 2007).

In December 2007, Ariba announced that it had completed the acquisition of Procuri, Inc. a privately held provider of on-demand supply management solutions, rounding out Ariba's offerings that help companies automate the procurement process. According to Ariba CEO Bob Calderoni, more than 70% of Procuri's 300 customers have under \$5 billion in revenues. As a result, this deal also gave Ariba greater access to midmarket customers (Anonymous, 2007). These strategic acquisitions helped Ariba to grow its line of products, as well as expand its customer base.

Consulting Adds Value

Calderoni believed that Ariba had the ability to not only survive, but thrive, by expanding beyond software that focused mainly on transactions, to encompassing and supporting additional facets of the buying process. Calderoni hired hundreds of consultants to advise companies on how to procure goods and services while incurring lower costs, using Ariba's software. Although consulting is generally viewed to be less profitable than selling software, Calderoni predicted he can successfully combine the two as an integrated set of offerings. While consultants coach Ariba's clients on how to use the software effectively, Ariba's clients can also interact and use Internet-based purchasing

systems to help them buy direct materials that are core to their company's manufacturing processes.

In order to extend Ariba's consulting services, which in 2004 accounted for nearly half of the company's \$323 million in sales, Ariba made consultants available via email and phone for a fraction of the price that is charged to the larger companies who require dedicated consultants through in site consultation visits.

Emphasis on the Customer

In 2001, investors were looking for a change in leadership at Ariba after the firm missed revenue and earnings projections by a wide margin. Ariba moved Keith Krach out of the CEO position, filling the post with the company's President and COO, Larry Mueller. Mueller entered the position with a new strategy: to halt the company's current plans to enter new markets, and instead opting to add new features, including electronic payment and invoicing, to its existing e-procurement and auction applications and offerings. Mueller heightened the focus on improving e-procurement applications by making heavy investments in existing e-procurement and sourcing platforms; and building technology around the key interactions that enterprises have with trading partners.

Mueller remained focused on bolstering Ariba's role as a traditional B2B transaction platform. Ariba announced plans to invest heavily in its *Ariba Commerce Services Network* and its network-centric applications, including *Network Connect*, which allowed non-Ariba customers to use the Ariba services network and conduct business or procure products and services. The company also focused its development, sales, and marketing staff to focus on specific industries. According to Mueller, "Customer ROI is the focus." A focus on international expansion boosted revenue from outside the US from 10% in the third quarter 2000 to 25% in the same period for 2001 (Purdum, 2007). Ariba was trying to rebuild its fortunes while the public marketplaces that used its technologies were struggling – an indication to

L

some economists that the industry may not have been ready for e-commerce.

Since joining the company in 2000 as chairman and CEO of Ariba, Mr. Calderoni has successfully transformed Ariba from a narrowly focused e-procurement vendor to a comprehensive spend management solutions provider that companies of all sizes rely on to transform the way they do business globally. Also, Ariba announced the availability of Chinese and Korean translations. Under Calderoni's leadership, Ariba has led the way in developing and delivering innovative solutions that combine technology, commodity expertise, and services to help companies streamline the procurement process and drive bottom-line results.

EXTERNAL FACTORS

Severe Competition

Simply being a dot-com business survivor, however, would not ensure its continued existence and profitability, and Ariba was at risk of losing business to the likes of other competitors such as SAP and Oracle. SAP, a German enterprise resource planning software maker, joined this market and signed on with Hewlett-Packard for a product called mySAP.com e-business solutions. In addition, it built a marketplace for chemical and pharmaceutical firms by educating them on mySAP.com, and with the result of installing a large SAP user base among Fortune 500 companies.

Nevertheless, Oracle had already anticipated a shift in the market and made plans to capitalize on it. Right now, the procurement sector is dominated by leading software companies Ariba and Commerce One. But as the slowdown in the U.S economy continues, Oracle was hoping that the opportunity for companies like Ariba would start to shrink as users look to more established ones, like Oracle, for an all-around e-commerce package (Arora, Greenwald, Kannan, Karthik, & Krishnan, 2007). Ariba had in fact provided Oracle

with an opportunity to gain market share when it cut a third of its workforce and announced reduced earnings during economic recent downturns.

Ariba recognized that to remain competitive, it had to address the problem of hidden costs associated with the products they sell, in addition to the price they charged for the software itself within the supply chain, especially when the product was in the later stage of its cycle. When a company does not pay much attention to the hidden costs of new software implementation, it can creep up and well-intentioned efforts can be result in financial penalties (Angeles & Nath, 2007; Brown, 2008).

By August 2008, the market for supply chain management (SCM) software market had grown. Worldwide spending on SCM solutions reached \$6 billion in 2007, which was up 17.6% from 2006. SCM Technologies was well-positioned to address the economic realities facing worldwide markets where costs were skyrocketing while competition and customer demands were intensifying (Eschinger, 2008). A number of the SCM solution vendors are merging, and expanding their capabilities within the realm of supply chain technologies. In comparison, Ariba's 2007 revenue was \$160.3 million, which significantly trailed behind Oracle and SAP, who reported \$955.2 million and \$1,334.4 million in revenue, respectively, showing that the threat of these products cutting into Ariba's bottom line is a real one (Orme & Etzkorn, 2007).

High-Priced Software

Without a doubt, e-procurement is rising substantially among the nation's largest 500 companies. Well-financed corporations are willing to invest in Internet software and technology that can reduce the inefficiency associated with the purchasing and buying processes. The use of this software can help companies to track spending and make sure they purchase products in accordance with contracts they have negotiated with suppliers. In fact, businesses that spend billions each year on supplies can often save tens of millions in costs

by implementing such technology. However, it's only the large firms that can devote the time and money to installing such systems, which frequently required that suppliers link to such systems as well (Janita & Miranda, 2013). Since the software is generally expensive and can be complicated to install on the customer's system, for small- and medium-sized businesses facing an uncertain economy, investments of this magnitude are can be difficult to justify.

Ariba took advantage of this situation, and in 2005 announced a strategy to sell its software and services to smaller companies on an on-demand basis, so they can buy supplies more efficiently online, as well. Ariba reshaped its software system so its customers can plug into Ariba's software through the Internet instead of installing it on their own systems. One major benefit of this approach, Mr. Calderoni said, is that Ariba can sell software to procurement managers and others in charge of spending, without involving the company's information technology staff.

Regulator's Investigation

In early 2003, Ariba came under investigation by the Security and Exchange Commissions (SEC). The reason for the investigation was linked to Ariba's accounting errors, doubtful partner deals, and questionable e-payments items including chartered airplanes. Among the specific allegations were that Ariba failed to record a \$10 million payment from Chairman Keith Krach to former chief executive Larry Mueller as an expense. The restatements are unusual because the chairman -- not the company -- covered the expense (Lau and Wang, 2007). Then three weeks later, Ariba decided to do the same for \$1.2 million in chartered jet services that was considered as Krach's compensation to Mueller, who subsequently left Ariba in July 2001. The problem was that United States laws and regulations require that payments by a principal holder to executives be treated as expenses paid on behalf of the company.

In addition, Ariba reported an additional \$7.5 million in expenses. In 2000, Ariba acquired TradingDynamic Inc., Tradex Technologies Inc., and SupplierMarket.com, and it reclassified stock options, or goodwill, that it gave to employees of these companies as a compensation expense. So by combining all of these expenses, the results were 18.7 million of added expenses. Ariba was aware that the regulator had begun an informal inquiry into its accounting practices after the firm said it would restate its earnings for 10 quarters.

Unhappy Customers

There have been some bumps in the road, including some public relations debacles. Ariba was subject to bad publicity after sending out automated emails to mid-size suppliers announcing their accounts had been upgraded to Premier level status. The email listed premier supplier benefits as well. However, the email also informed them that as a Premier Member, they were now required to pay associated annual fees. Many of the small and mid-size companies viewed this as a marketing ploy and felt they should not be made to pay for the upgrade without prior consultation or the ability to decide whether an upgrade was desired (Eschinger, 2008).

FUTURE RESEARCH DIRECTIONS

Ariba has thrived on making strategic, yet controversial decisions throughout the years. Having gone through ups and downs during the years, they still managed to largely maintain a leadership position even though markets and needs have evolved and changed. Overall, they have been able to provide customers with superb services and innovative products, and reliability is what keeps old customers, and helps to bring in new customers.

According to Jin and Yu (2015), procurement auctions have gained significant momentum over

the last two decades. So it remains to be seen whether Ariba keep its promise of:

Using the Ariba Network - anytime, anywhere - you can connect with your trading partners to buy smarter, sell faster, and manage your cash more efficiently and effectively than ever before? (Ariba, 2014)

CONCLUSION

Ariba achieved recognition for its *Supplier Network*, an e-business center where millions of buyers and suppliers can electronically transact business online, with the goal of more efficient procurement. In addition, Ariba developed spend management software, and took this kind of network mainstream. Ariba's application-driven strategy of an open platform, hosted and implemented by partners with vertical-market domain expertise, has helped to secure them a dominant position in the B2B e-commerce application marketplace.

It is interesting to note that while many firms who came up around the time of Ariba and offered competing solutions, Ariba is one of the few that has survived and thrived, using continually new strategies to stay in business, providing a better customer experience, and utilizing advances in technology and ideas that no other companies dared to try. Ariba has been, and remains, a pioneer and a leader in an exceedingly competitive and changing marketplace. Due to increased globalization and deregulation, for a company to succeed, it needed to maintain leverage over the impact of competitive forces. Ariba has done a great job in setting themselves apart from their competitors by strategically aligning themselves with their partners, and also expanding its service offerings to a wider range of customers. Ariba's software offerings help companies focus on profitability, and together with its wide array of service options, are customizable for both larger and smaller companies. The firm's products are concrete and

customizable, depending on a client's needs. In addition, the product offerings are offered on a common platform, allowing information to travel accurately and quickly through the supply chain.

KEY TERMS AND DEFINITIONS

Acquisition: Acquiring control of a corporation, called a target, by a stock purchase or exchange, either hostile or friendly.

Business to Business (B2B): The exchange of products, services, or information between businesses.

E-Commerce (Electronic Commerce or EC): The buying and selling of goods and services over the Internet.

E-Payments (Online Payments, Electronic Payments, Internet Payments, Web Payments, and ePayment): An electronic payment made via

a web browser for goods and services using credit or debit cards or other related payment means.

E-Procurement: A system utilizing Internet technology to streamline the purchases of goods and products in order to reduce costs.

Supplier Network: A network of screened and qualified small-scale producers and committed medium-sized suppliers.

Supply Chain Management (SCM): The process of strategically managing flows of goods, services and knowledge, along with relationships within and among organizations, to realize greater economic value.

L

An Integrated Approach to Supply Chain Simulation

Nenad Stefanovic

University of Kragujevac, Serbia

Bozidar Radenkovic

University of Belgrade, Serbia

INTRODUCTION

Simulation can be a valuable tool for supply chain analysis, planning, optimization, evaluation, and risk management. Computer simulation and simulation models can be used to model intricate supply chains close to real systems, execute those models, and observe system behavior. The goal of simulation is to evaluate existing supply chain configurations, as well as to aid in design of the new supply chains. Supply chain simulation matters both supply chain design and supply chain control. In other words, it helps resolve different supply chain management (SCM) problems which can be grouped into the following categories:

- Infrastructure configuration that implies defining of the manufacturers, distribution centers, wholesalers, retailers and their locations (nodes).
- Planning and design of supply networks.
- Defining strategy related to processes at the nodes.
- Coordination between processes and activities with the purpose of their alignment and fulfillment of performance goals on global supply chain level.
- Information integration so that processes can exchange all necessary information.
- Risk mitigation in supply chain implementation both at the strategic and process levels.

- Supply chain validation through performance measurement which involves defining metrics at different supply chain levels.
- Validation through performance monitoring which involves defining metrics at different supply chain levels.
- Optimization by means of what-if analysis and application of best practices for improvement.

Modeling and simulation approach is the only practical option for exploring performance of the complex business networks such as supply chains. Furthermore, the modeling and simulation approach facilitates the design of the new supply chain configuration and policies, as well as the redesign of existing systems (Thierry et al., 2010). There are different supply chain modeling methods and types of simulation. Supply chain simulation can be performed with different goals. This can be analysis of supply chain dynamics, structure, or cash flow, risk mitigation, design, learning, etc.

In this chapter, the modelling approach and the simulation software which has integrative features capable to unify these various needs for different user groups are presented.

The background section gives definitions and explanations of key terms and concepts, as well as literature review with main contributions related to supply chain simulation. Simulation software integrates different models, entities and modules that function cooperatively. Its construction and

functioning principles are described and examples of supply chain simulations are given. The key contributions and benefits of the presented simulation solution are presented. Finally, the main future research directions and opportunities are examined.

BACKGROUND

By examining well designed simulation models, organizations can reinforce their decisions regarding supply chain processes. They can study and analyze effects of different supply chain initiatives and improvement programs through sensitivity analysis (such as what-if or goal seek) before investing huge amount of money or disrupting their operations.

Computer simulation and simulation models can be used to model intricate supply networks close to real systems, execute those models, and observe system behavior.

The main advantages of the supply network computer simulation are (Stefanovic et al., 2009):

- The simulation is relatively clear and flexible.
- It can be used for analysis of the complex real systems such as supply networks.
- With the simulation, it is possible to include real-world influences, for example uncertainty factor in demand or lead time.
- “Time compression” is possible. Effects of a certain business policy over a long period of time (months, years), can be obtained in a short time.
- The simulation enables “what-if” analysis. Managers can test the results of different decisions.
- The simulation does not interrupt real systems. For example, experimenting with different supply network configurations can be done without disruptions and significant investment.

- With the simulation, the effects of the individual components, parameters and variables can be studied at the global level.
 - The main disadvantages of the supply network computer simulation can be summarized as:
- Quality simulation models can be expensive and time consuming to develop and validate.
- This is “modify-try” approach. Typically, it does not generate optimal solutions.
- It is necessary to model and define all relevant data in order to produce valid results which can be very difficult in complex supply network scenarios.
 - Simulation models can be classified into several categories and based on more than a few ways. Kleijnen (2005) classifies simulation models into four types:
- **Spreadsheet Simulation:** Used in corporate modeling usually by managers;
- **System Dynamics (SD):** Organizations are viewed as systems with six types of flows: materials, goods, personnel, money, orders, and information;
- **Discrete-Event Dynamic Systems (DEDS) Simulation:** Incorporates uncertainties and is usually part of the ERP systems;
- **Business Games:** Interactive simulation where managers operate within the simulated ‘world’.

During the past few decades, a number of papers have been published that deals with different aspect of supply chain modeling and simulation.

Some of them are purely mathematical models using the linear or mixed integer programming (Ettl et al., 2000), which are not fully applicable in a complex and volatile business environment. Those mathematical models have quite limited modeling power because they are based on simplifying assumptions and typically do not support

uncertainty (Buckley & An, 2005). Some authors proposed a hybrid approach combining analytics and simulation methods for solving production–distribution problems in supply networks (Lee & Kim, 2000).

Tunali et al. (2011) applied a hybrid model which combines mathematical modeling and simulation in a produce-to-order manufacturing company. First, a mathematical model is used to generate production and distribution plans while minimizing costs. Based on these plans, optimal scheduling decisions are made. Finally, the dynamic and stochastic simulation is used to assess these decisions.

Li et al. (2012) used stochastic network mathematical model for analyzing the ordering dynamics and for identifying the key links in ordering networks. Based on these models and using simulation, effect of different ordering policies on economic performance of multi-stage supply chain are evaluated. The goal is to produce a decision support system for designing effective strategies to improve supply chain performance. The use of simulation for understanding the performance of supply chain collaboration is relatively a new approach and this can be used by companies that are interested in collaboration without having to invest a huge sum of money in establishing the actual collaboration (Ramanathan, 2014). Cigolini et al. (2014) used discrete event simulation along with scenario design technique and statistical analysis for studying how supply chain configuration and management decisions impact supply chain performance. The results showed that information sharing and coordination have very positive impact on supply chain performance.

Shukla et al. (2010), introduced a hybrid approach that incorporates simulation to a comprehensive supply chain network, Taguchi method to quickly determine a robust area and optimize qualitative factors, regression analysis and Psycho-clonal algorithm which refines the result obtained by Taguchi orthogonal array. The goal is better understanding the dynamic relationships of different factors in supply chains, decreased

influence of uncertainty, and determination of production capacities. Sahay and Ierapetritou (2013) proposed a hybrid approach which combines a mathematical programming model with an agent-based simulation model and uses them in an iterative framework. The optimization model is used to guide the decisions toward an optimal allocation of resources given the realistic supply chain representation given by the simulation.

The lack of a standard way for modeling and analysis of supply networks resulted in a variety of methods for developing supply network simulation models. SCOR (Supply Chain Operations Reference) model, as a widely accepted industry standard can serve as a good starting point for designing supply network simulation software and frameworks. The e-SCOR modeling and simulation environment (Barnett & Miller, 2000) is based on the SCOR model and built upon a discrete event simulator. Herrmann & Pundoor (2003) presented the supply chain simulation framework that follows the SCOR model and that integrates discrete event simulation and spreadsheets. Because of the complexity and low usability of the distributed simulation models, a new approach based on ontologies to integrate several supply chain views and models, which captures the required distributed knowledge to build simulation models, is proposed. Persson et al. (2009) presented modeling of supply chain structure based on the SCOR model and application of discrete simulation. They used the ARENA commercial simulation software and limited number of the SCOR processes.

Agent-based distributed simulation can be very useful for modelling and analyzing such complex adaptive systems as supply chain networks. Long (2015) proposed a methodology for distributed supply chain network modelling and simulation by means of integration of agent-based distributed simulation and an improved SCOR model. This approach enables accelerated flexible supply chain modeling and reuse of simulation models. Nikolopolou and Ierapetritou (2012) proposed an agent-based hybrid simulation optimization

approach that addresses the problem to the operational/tactical level of the supply chain management. The main criterion is cost minimization. One of the constraints of this approach is that it does not take into account stochastic nature of supply chains.

Thanks to their main characteristic (autonomy, interactivity, and reactivity), agents and multi-agent systems (MAS) are well-suited for modeling and simulating the dynamic behavior of supply networks (Swaminathan, 1998). These approaches are used for simulating different business scenarios such as harbor supply chain management (Yi et al., 2002), warehouse inventory planning and materials handling (Ito & Abadi, 2002). In multi-agent systems, business entities are represented as agents, and the involved information and material flows with proposed coordination method for collaborating among agents. Labarthe et al. (2007) proposed an agent modeling framework for the modeling and simulation of supply chains. The software presented makes use of collaboration between cognitive and reactive software agents. Chatfield et al. (2007) introduced the order-centric conceptual architecture that combines simulation formalisms to represent supply chain infrastructure (nodes, actions, policies, etc.). It consists of the knowledge base implemented as a specific XML dictionary called Supply Chain Markup Language (SCML), and the Java-based simulation engine used to transform the SCML files and to run the simulation (Chatfield et al., 2004).

Jiang et al. (2009) considered dynamic inventory control and non-stationary customer demand in order to achieve a preset customer level. The case-based reinforcement learning method is used. They used multi-agent simulation to analyze different inventory replenishment policies of a simplified two-echelon supply chain. Limitations of the simulation model are the number of nodes, as well as the number of goals.

Another example of the XML-based simulation is Simulation Markup Language (SML), an open-source tool (Kilgore, 2001), and Manufacturing Information Model for Simulation (MIMS) (Qiao & Riddick, 2004) that enables design of the platform-neutral supply chain model that can be further transformed to suite the schema of the particular simulation software tool.

Ding et al. (2005) based on analysis of existing literature noted that existing models lack general applicability and stressed the need for a general approach for both supply chain modeling and its evaluation by simulation. They proposed discrete-event simulation software made of a number of different building blocks (enterprises, suppliers, manufacturers, distributors, etc.)

Other papers are based on the “beer game” method, most often used in experiments that consider small number of elements for analysis in relation to certain limited number of influence factors, such as POS (point-of-sale) information and customer demand pattern (Fayez et al., 2005).

Due to supply chain complexity (more and more people use the expression: supply network) a great deal of existing simulation approaches and solutions deals with only particular SCM segments, presume assumptions that make simulation models less realistic and usable for practical application and with reduced opportunities for validation of derived results. They usually take into consideration only a single product, whereas in real systems there is a concurrency (multiple products) for resources. Also, there are considerable limitations in terms of experimenting with various supply chain structures and policies.

The following section provides an overview of computer-based supply chain simulation which is based on discrete-event simulation, process approach and intelligent system for event management. The proposed methodology and software solution enable fulfillment of the goals described in this section.

SUPPLY CHAIN MODELING AND SIMULATION

Characteristics of the Simulation Software

Supply chain simulation software solution should fulfill the following requirements:

- It should provide intuitive and straightforward modeling environment.
- To be intuitive and simplified for the end-users.
- It should enable modeling of any supply chain structure regardless of its complexity in terms of number of levels, nodes at each level, products, business policies, etc.
- It shouldn't be constrained by number of different elements such as products, participants or relationships.
- Ability to store models and simulation results in database.
- Simulation models should be close to corresponding real-world systems – they should embody various constraints, technologies and organization.
- It should enable performance measurement through appropriate metrics and at different levels.
- Beside sensitivity analysis, it should enable design of new supply chains, as well as learning by experimenting.
- It should be useful for wide range of users – researchers, business people, educators, consultants, etc.

Supply chain complexity represents the main obstacle in fulfilling these requirements. Solution presented in this chapter is based on process approach, system decomposition into modules, SCM Metamodel, application of intelligent decision mechanisms and expert systems, as well as application of standards.

Process Approach

Many of today's well-known business models and standard initiatives such as SCOR (Supply Chain Operations Reference), ODETTE SCMo (Supply Chain Monitoring), RosettaNet, and ebXML are based on process approach.

SCOR model represents a universal approach to supply chain management that can be applied in diverse business domains. Supply Chain Operations Reference (SCOR) model integrates the well-known concepts of business process reengineering, benchmarking, and process measurement into a cross-functional framework, and represents an industry standard. This standardization movement facilitates the deliverance of business content for the supply chain simulation model.

A process reference model contains (SCC, 2010):

- Standard descriptions of management processes.
- A framework of relationships among the standard processes.
- Standard metrics to measure process performance.
- Management practices that produce best-in-class performance.
- Standard alignment to features and functionality.

According to SCOR, supply chain management consists of the following integrated processes: Plan (P), Source (S), Make (M), Deliver (D), and Return (R) – from the suppliers' supplier to the customers' customer, and all aligned with a company's operational strategy, material, work, and information flows. Additionally, SCOR includes a series of Enable (E) elements for each of the processes. Enable elements focus on information policy and relationships to enable the planning and execution of supply chain activities (Bolstorff & Rosenbaum, 2003). SCOR contains three levels

of process detail. The top level defines scope and content of the supply network. This is where the bases for the performance targets are set. At the second level, the intersection of process and process types forms process categories. The third level consists of the actual process elements and their process flows. It is this bottom level of the SCOR model that is the most significant to the simulation. Process elements are the most granular detail of the SCOR model and serve as the first level of process decomposition. Each process element has the following attributes: process ID, process name, standard definition, performance metrics, best practices (where applicable), and finally, inputs and outputs.

Software Solution for Supply Chain Simulation

Simulation software that is introduced covers a wide range of simulation categories in the supply chain domain. Additionally, it meets a series of additional conditions.

One of the most important is the closeness of the simulation models with real supply chain systems. Supply networks have complex structure in terms of number of nodes and levels in which they are in. At nodes, multitude of different processes with large number of transactions are perform. Furthermore, final products with complex bill of materials structure are often represented. The real systems exists in an environment with various constraints such as financial, operational, warehousing, and transportation capacities, as well as those related to energy and human resources.

The next group of conditions is related to modeling and simulation. Modeling is performed in a way close to the business user who can completely dedicate in solving SCM problems. Metrics harmonized with existing standards assists in interpretation of results.

The basic components of the simulation software (Stefanovic & Stefanovic, 2015) are further described.

Information system for supply chain simulation consists of the following interconnected modules within the supply network Metamodel: SCOR (Supply Chain Operations Reference) model, information system entity submodel, business environment submodel, constraints submodel, simulation module, module for assessing and improving the supply network instances and training (education) submodel. The Metamodel contains the complete SCOR model structure.

Entities of the information system are designed in such a way that enables modeling of large number of real supply networks in various business domains.

Business environment submodel represents setting in which supply network entities exist. It is expressed by the available resources such as employed capacities, financial capital, human resources, materials, and energy.

The constraints submodel represents constraints for each process and it is expressed by the amount of engaged resources. Constraints can be technical, technological, financial, and organizational (Stefanovic & Stefanovic, 2009).

The simulation submodel integrates supply network structure, characteristics of processes in nodes, and entities that correspond to the simulation methodology. Process characteristics are associated with SCOR best practices, but besides that they also include other process implementations from theory and practice. All these forms the process library.

The simulation submodel is also responsible for realization of simulation methodology. The methodology is based on discrete event simulation and process approach. Its most important part is specific expert system which manages process interactions. The structure of the expert system consists of the knowledge base and the conclusion engine. The basis for the process interaction is the specialized three-phase rule (Stefanovic & Stefanovic, 2008).

The module for assessing and improving the supply network instances includes an intelligent

system that is rule-based and consists of several steps. The first step identifies a set of metrics that do not meet predefined goals. The second set of rules establishes relationship between the set of metrics obtained at the first level of rules and corresponding processes at each location. The third set of rules establishes a connection between the resulting set of processes and best practices. The fourth set of rules relates best practices with the performance attributes and their characteristic. Performance attribute characteristic for a given best practice shows whether the performance attribute increases or decreases. This way, from the set of best practices and for all processes on all locations, appropriate best practices whose value is increases are selected (Stefanovic & Stefanovic, 2013).

Simulation process involves modeling, simulation execution, as well as reporting and analysis of the results. Modeling process includes modeling of supply network structure (structure submodel), process modeling (process submodel), resource modeling (resource submodel), and constraints modeling (constraints submodel). Structure submodel encompasses supply network nodes (suppliers, manufacturers, distribution centers, wholesalers, retailers, etc.) and their relationships. Process submodel is composed of processes at each node and their connections. Processes correlate to the SCOR Level 3 processes. Within the submodel, characteristics for each process are determined. Modeling is carried out until the level of the single product, which also contributes to the realness of the simulation model.

Simulation execution comprises a set of activities that carry out the simulation. Important elements for simulation execution are also external events, generation of initial conditions and waiting queues. External events can be customer demand or delivery of the purchased materials. They trigger other events in the system. External events can be generated in one of the three ways: by Monte Carlo method, by generating random values, or they might be predefined. Initial conditions are starting inventory of products and materials

(semiproducts), parameters of specific reorder policy (i.e. order quantity, reorder level, lead time), customer backorders, unfulfilled supplier orders, number of work shift, etc. Waiting queues occur when a certain process should start, but at that moment resources are engaged for another product for which the executing has already begun (Stefanovic & Stefanovic, 2013).

Reporting of simulation results include a set of information like values of SCOR metrics, fluctuation of inventory levels at each location and for each product, cost overview, profit, waiting lines, etc.

It can be noted that the simulation method and the software solution are quite complex and that they integrate several components into the unique system (Figure 1).

This gives possibility to perform a wide spectrum of supply network simulations, as well as convenience for different groups of users. Integration can be seen from the Metamodel itself. It contains the information system with entities that can cover wide range of supply network configurations. The Metamodel integrates supply network structure, processes, resources, constraints, technologies, organization, best practice and metrics. Furthermore, many of the established methods for particular processes are included in the simulation model. For example, different inventory replenishment models, models for solving transportation problems, reception of materials, warehousing, etc. Also, this way it is possible to test these models and to make comparisons. Evidently, it is possible to model some less complex systems, such as pure production or distribution system, or to test specific mathematical model for inventory replenishment by selecting appropriate processes.

Examples of Supply Chain Simulation

- **Reducing Risks of Implementing Supply Networks at Different Levels (Strategic, Tactical and Operational):** Every experimenting with supply networks in real

Figure 1. Architecture of the information system for supply network modeling and simulation

environment is very risky and can lead to huge losses and disruptions. In this regard, simulation offers many opportunities to completely avoid or to reduce mistakes and wrong decisions. It is very crucial how supply network is going to be organized, integrated and managed. Also, each process could have many forms which also can be tested through simulation (Stefanovic & Stefanovic, 2013).

- **Analysis of System Dynamics Through Uncovering Relationships and Interdependence Between Processes:** System dynamics manifests in many forms. For instance, different mathematical models for inventory management (i.e. FQS-Fixed Quantity System or FPS-Fixed Period System) contained within the purchasing process are tested in distribution systems.

They are combined with various characteristics of other processes: order fulfillment, shipment, receiving, etc. (Stefanovic & Stefanovic, 2008). Another example is testing of various supply network structures for different versions of replenishment and order fulfillment processes (Stefanovic & Stefanovic, 2009).

- **Infrastructure Configuration which Implies Arrangement of Producers, Suppliers, Distribution Centers, Wholesalers, Retailers and Their Locations (Nodes):** For single complex supply network different structures can be configured. This includes number of suppliers, location strategy, number of distribution centers or retailers, etc. Each of these configurations can be evaluated before making final decisions.

- **Defining Process Strategy at the Nodes and Coordination Between Processes with the Purpose of Their Alignment and Achieving Goals at the Global Supply Network Level:** Single process (or node) optimization does not necessarily mean the best results at the global level. It is necessary to align process characteristics in order to maximize results at the supply network level. For example, in certain cases the FQS system will produce better results, and in other the FPS system will perform better (Stefanovic & Stefanovic, 2011).
- **Analyzing Effects of Information Sharing:** It is possible to simulate different degrees of information sharing (visibility) among processes and supply network nodes and to observe effects of information sharing and to make decisions about what information should be shared and between what processes. This could significantly reduce the bullwhip effect and improve coordination of supply network activities.
- **Evaluation of Supply Network Through Performance Monitoring which Involves Defining the Metrics at Different Supply Network Levels:** Performance measurement is carried out according to the SCOR metrics (Stefanovic 2014), and also with other metrics available from the literature such as profit, stock level, capacity utilization, etc. (Stefanovic 2015).
- **Supply Network Design:** Besides supply network testing, methodology for designing supply networks has been also defined. It utilizes simulation for validation of the design. The process includes defining the supply network structure, processes in nodes and their relationships, process characteristics and resources that are engaged, according to the project goals. Additionally, constraints can be taken into consideration (Stefanovic & Stefanovic, 2013).
- **Training and Learning About Supply Chain Management:** Simulation software enables learning at different levels. First, it provides studying the SCOR model. All the standard information from the SCOR model can be obtained and also to make intelligent search. For example, users can obtain answers to questions such as: What processes influence cost reduction in supply chain? Besides this static learning, interactive learning based on simulation is also possible. The most useful case is using the simulation for understanding SCM processes and characteristics such as uncertainty and bullwhip effect.
- **Cash Flow Simulation:** Cash flow simulation is one of the future research projects. The simulation software includes necessary elements for experimenting in this domain, that is, it encompasses processes and metrics related to cash flow. These elements are integrated with other processes and metrics, so the cash flow is not analyzed separately. Cash flow simulation is integral part of the overall supply network simulation. Cash flow is observed from a point of taking actions for mitigating risk of running out of cash in certain period. This way, it is possible to analyze cash flow in relation to various variables like initial stock or purchase price.

Based on the described simulation scenarios it can be concluded that besides integrativity of the software itself, there is integrativity in terms of problem that can be analyzed and solved. In other words, by creating models for specific goals, it is also possible to obtain the complete set of results for other business needs.

Presented simulation software fulfils main requirements for efficient and effective supply chain simulation which is demonstrated in several research results (Stefanovic & Stefanovic, 2008; Stefanovic et al., 2009; Stefanovic & Stefanovic, 2013). It is flexible enough to be applied in vari-

ous supply chain networks regardless of the size, structure, complexity and dynamics. Here are some of the application examples:

- Measuring influence of different supply chain process types, their relationships and realization methods at the global level. These involve various replenishment models, order processing, shipment, initial stock and lead time. Some of the metrics include costs, profit and serviceability.
- Analysis and assessment of supply chain structures in terms of different inventory management models. Performance measures are based on the SCO metrics.
- Analysis and assessment of supply chain performance in situation where there is a concurrent usage of production capacities and other resources which results in waiting queues. Besides standard SCOR-based metrics, the metric which shows the waiting duration of certain products and components during the process execution.
- Supply chain design and reengineering using an intelligent modeling and simulation system.

On the other hand, the software can be used by different user groups such as supply chain architects, managers, people working in logistics or operation research, as well as students.

FUTURE RESEARCH DIRECTIONS

As supply chain management is becoming more and more critical for businesses, methods, techniques and tools for managing and analyzing these complex business networks will be topic of extensive research and development in years to come. Having in mind successful applications of simulation tools and models so far, simulation will definitely be important segment of this research. The future research trends can be categorized in the following areas:

- Supply chain modeling
- Standardization
- Integration of simulation models
- Intelligent analysis and optimization

Regarding the presented simulation approach, future research directions will be directed toward two main segments: first segment relates to experimenting, and the other relates to data analysis and mining. The new experiments will be focused on analysis of supply chain financials (costs and cash-flow), as well as supply chain information exchange and coordination (i.e. bullwhip effect). Considering that simulation software enables efficient modeling and simulation it is possible to create many models which are stored in the model library along with simulation results. These data sets can be used in conjunction with data mining tools in order to extract new knowledge, find hidden patterns and predict future.

CONCLUSION

Supply chain management in today's business climate characterized by high uncertainty, globalization of business, outsourcing, shorter product life-cycles, and high customer expectations is extremely challenging. Companies are now competing as parts of a supply chains and there is a growing need for the global planning and management of the distributed and intertwined supply chain processes.

High complexity of supply networks and the need for applying logistic principles (global approach, effectiveness, and efficiency) have led to an array of significant research domains that are directed toward improving the supply network performance. Many of this research efforts are based on simulation.

That is why the goal was set to develop the methodology and the software solution that would encompass as many of the important domains of supply network simulation application. This resulted in integrative simulation software capable

to support various simulation needs. It can be used for modeling, execution and analysis of simulation results. Modular structure of the software enables modifications and further extensions with the purpose of supporting future research projects related to SCM.

Simulation can be used to more scientifically decide how to modify processes and improve supply chain operations. Newer change-decision models incorporate simulation into the analysis. Applied within the context of experience, simulation can help organizations to analyze different supply chain scenarios, reduce costs, manage risk, diminish problems and ensure market share.

This chapter deals with supply chain simulation, provides literature review and presents unique approach for supply chain modeling and simulation. This approach offers:

- **Flexibility:** Any supply chain configuration can be modeled.
- **Extensibility:** Model database and business logic can be extended.
- **Expressiveness:** Models embody all important characteristics.
- **Authenticity:** Simulation models and execution are close to real systems.

The developed software solution enables straightforward and efficient modeling of supply chain structure and dynamics, as well as experimenting through simulation execution and analysis of results.

KEY TERMS AND DEFINITIONS

Business Process: A business process is a complete set of end-to-end activities that together create value for the customer.

Knowledge Base: A specialized database that serves as repository for information and knowledge management.

Metamodel: A conceptual model which defines concepts, relationships, and semantics and enables creation of concrete models.

Metric: A measure of particular process characteristic.

Model: A model is a simplified representation of a system at some particular point in time or space intended to promote understanding of the real system.

Performance Measurement: A process for collecting and reporting information regarding the performance of an individual, group or organizations. It can involve looking at process/strategies in place, as well as whether outcomes are in line with what was intended or should have been achieved.

Simulation: Simulation is defined as the process of creating a model of an existing or proposed system in order to identify and understand those factors which control the system and/or to predict the future behavior of the system.

Supply Network: Dynamic, interconnected and collaborative group of companies working jointly on planning, management and execution of cross-company business processes spanning from the first tier suppliers to the end-customers.

INTRODUCTION

Nowadays, the increased demand for energy and goods around the world has made the business environment more and more complex concerning the design and operation of power systems, supply chain and transportation networks, production scheduling of factories etc. This complexity has made real case studies increasingly difficult to solve due to the large-scale mathematical models constructed. These models do not only depend on the number of parameters, decision variables and constraints. Frequently, even if these features are moderate, optimization problems could still be considered as large-scale due to complicating structures making their solution hard to get.

Information Science and Technology together with Operations Research and Mathematical Programming can show the way towards better solutions in all fields of economy. Nowadays, the evolution of computers combined with mathematical decomposition techniques can solve real size mathematical models and optimize the operation of real-life systems by e.g. avoiding an unpleasant outcome, decreasing operations cost or increasing the overall profit.

The mathematical decomposition techniques aim at decomposing the initial large-scale mathematical model into two or more sub-models based on mathematical programming theorems, as for example, the duality theorem. In principle, the mathematical decomposition techniques do not depend on the case study, but on the structure

of the developed mathematical model, which describes the system under study. Mathematical decomposition techniques are:

- Benders decomposition (Benders, 1962),
- Dantzig-Wolfe decomposition (Dantzig & Wolfe, 1960),
- Lagrangian relaxation,
- Lagrangian decomposition and
- Cross decomposition.

The main goal of this chapter is to present the Benders decomposition method, identify its weaknesses and display all the recent research made to tackle them.

In the next section, a very brief literature review on the method is provided. Following, the method is presented and explained together with its main weaknesses. The same section includes the latest advances from the literature, which address these weaknesses. The next section, future and emerging trends on Benders decomposition are discussed. Finally, the chapter is concluded at the final section.

BACKGROUND

Benders decomposition technique was introduced by (Benders, 1962) for linear problems with coupling integer variables. Although the algorithm was initially used for block-decomposed large-scale optimization problem, lately the algorithm

has been applied also in other types of problems. The Benders method has been applied successfully to stochastic programming (Watkins, McKinney, Lasdon, Nielsen, & Martin, 2000) for the solution of multi-scenario, two-stage and multistage stochastic problems where the scenarios are split to sub-scenarios and studied separately decreasing the amount of data taken under consideration in each optimization step; to global optimization problems (Zhu & Kuno, 2003) to address the non-convexity nature of big data; and more recently to build mathematical models (Ierapetriou & Saharidis, 2009), where a large amount of experimental data are available for model building.

BENDERS DECOMPOSITION APPROACH

Presentation of the method

The Benders decomposition (Benders, 1962) technique is based on the idea of exploiting decomposable structure of a given problem so that its solution can be converted into the solution of several smaller sub-problems. Table 1 shows this block-decomposable structure, where A is the matrix of the constraints coefficients.

For the construction of the subproblems, certain variables of the original problem are considered to be complicating. By fixing them, the original problem is decomposed into the Relaxed Master Problem (RMP), which contains only the complicating variables, and the Primal Sub-Problem (PSP), which contains the rest of the variables. Thus, RMP is a relaxation of the original problem and is expected to provide the optimal solution after the addition of a number of constraints (i.e. inequalities).

Without loss of generality, one could consider the following linear problem:

Original Problem (OP):

$$\text{Min } c^T x + d^T y$$

st.

$$Ax + By \leq b$$

$$x \in \mathbb{R}_+^n, y \in \mathbb{Z}_+^q$$

where $c \in \mathbb{R}^n, d \in \mathbb{R}^q, b \in \mathbb{R}^m$, A and B are $m \times n$ and $m \times q$ matrices respectively.

Assuming vector y contains a number of decision variables, which are considered to be complicating, the decision variables are partitioned into two sets x and y and the OP decomposes into the following problems:

Primal Slave Problem (PSP):

$$\begin{aligned} \text{Min } f(x) &= c^T x + d^T \bar{y} \\ \text{st.} \\ Ax &\leq b - B\bar{y} \\ x &\in \mathbb{R}_+^n \end{aligned}$$

Where $\bar{y}$ is the fixed values of the complicating variables, obtained by solving RMP.

Relaxed Master Problem (RMP):

$$\begin{aligned} \text{Min } F(y, z) &= z \\ \text{st.} \\ v^{iT}(b - By) &\leq 0 \\ u^{jT}(b - By) + d^T y - z &\leq 0 \\ z &\geq 0, y \in Z_+^q \end{aligned} \left. \vphantom{\begin{aligned} \text{Min } F(y, z) = z \\ \text{st.} \\ v^{iT}(b - By) \leq 0 \\ u^{jT}(b - By) + d^T y - z \leq 0 \\ z \geq 0, y \in Z_+^q \end{aligned}} \right\} \text{Benders Cuts}$$

where v^i is the vector that corresponds to the extreme ray i of the dual of PSP and u^j is the vector that corresponds to the extreme point j . An extreme ray (point) is a ray (point) that cannot be expressed as a linear combination of any other rays (points).

The dual of PSP has the following form:

Dual Slave Problem (DSP):

$$\begin{aligned} \text{Min } f'(u) &= u^T(b - B\bar{y}) \\ \text{st.} \\ A^T u &\geq c \\ u &\in \mathbb{R}^m \end{aligned}$$

The Benders decomposition algorithm is an iterative algorithm. In each iteration, the RMP is solved and its solution (the values of the complicating variables) is transferred to the PSP. Afterwards, the PSP is solved. If the PSP is infeasible (DSP is unbounded), a *Benders feasibility cut* is created ($v^{iT}(b - By) \leq 0$), where v^i is the vector that corresponds to the extreme ray i of DSP. The feasibility cut is then added to the RMP. If the PSP is feasible (DSP is bounded), a *Benders*

optimality cut is created ($u^{jT}(b - By) + d^T y - z \leq 0$), where u^j is the vector that corresponds to extreme point j of DSP. The optimality cut is then added to the RMP. Thus, in each iteration RMP incorporates new constraints, so more information about the solution space of the OP. Afterwards, the enriched RMP is solved again and the procedure is repeated.

In each iteration in the case of minimization (-maximization), the RMP gives a valid lower (-upper) bound as a relaxation of the original problem and the SP gives a valid upper (-lower) bound as a restriction of the original problem. Thus, the convergence criterion for the termination of the Benders algorithm is defined based on the difference between the minimum upper (-lower) bound and the current lower (-upper) bound. When this difference is lower than a small number or equal to zero the algorithm stops, otherwise it continues. In Figure 1, Benders decomposition algorithm is described using a flowchart.

One could observe that during the iterations of the algorithm only the objective function of DSP is updated, as the constraints are not modified. This means that the solution space of DSP is always the same. If all possible Benders cuts were produced using all the extreme points and extreme rays of the DSP solution space, then the resulting augmented RMP is an equivalent version of OP and its solution yields the same optimal solution as the OP. The total number of Benders cuts, which equals the number of extreme points and extreme rays of DSP is, generally, enormous. However, it is known that at the optimum the number of RMP active constraints will never exceed the number of RMP decision variables (Saharidis, Minoux, & Ierapetritou, 2010). The main idea of the Benders algorithm is based on the observation that the algorithm will converge, satisfying the optimality condition before the addition of all Benders cuts. Note that the finite convergence of the algorithm results from the fact that DSP has a finite number of extreme points and extreme rays.

Figure 1. Flowchart of the Benders Decomposition Algorithm

Main Weaknesses of Benders Decomposition Algorithm

Benders decomposition has been applied in a lot of cases with notably good results (Conejo, Castillo, Minguez, & Garcia-Bertrand, 2006). However, in some cases the straightforward application of the classical Benders algorithm does not lead to fast convergence (Saharidis, Minoux, & Ierapetritou, 2010). A lot of publications exist to support the fact that Benders algorithm has not been uniformly successful in all the applications and has some deficiencies.

The main issues associated with slow convergence of the Benders algorithm (Saharidis & Ierapetritou, 2010) are:

1. The solution of resulted sub-problems and
2. The quality of the cuts produced in each iteration

Solution of Sub-Problems

As discussed in the previous section, during the application of the classical Benders algorithm, two problems are solved in each iteration, i.e. the RMP and the PSP. In many cases, the PSP and RMP are hard to be solved to optimality. The most frequent problem is the solution of the RMP which is usually an integer problem and should be solved in every iteration of the Benders algorithm.

For tackling this difficulty, (McDaniel & Devine, 1977) proposed the generation of cuts by relaxing the integrality constraints of the RMP. The integer restrictions of RMP are dropped for some iterations of the algorithm and in order to converge to optimality they are reinserted. The presented results appeared to be promising, although in some cases the classical algorithm can still be more efficient.

(Cote & Laughton, 1984) proposed three heuristic approaches to solve the RMP using the obtained solution to generate the Benders cuts from the PSP. The application of their three approaches has demonstrated very good results.

The weak lower bounds (in case of minimization) obtained by the RMP is another reason leading to slow convergence of the Benders decomposition algorithm, due to the many iterations (thus many solutions of RMP) needed to reach convergence. The development and introduction of valid inequalities to the RMP, eliminating a priori a number of infeasible solutions, is a successful strategy to lessen the number of iterations and, thus speed-up the Benders decomposition algorithm producing stronger lower bounds. (Cordeau, Soumis, & Desrosiers, 2000) added three sets of valid inequalities to RMP accelerating the convergence to the optimal solution of the locomotive and car assignment problem. (Cordeau, Pasin, & Solomon, 2006) introduced a new formulation of the logistics network design problem, where the Benders decomposition algorithm is applied and a series of valid inequalities are presented as the part of the solution methodology. (Andreas & Smith, 2009) presented a series of valid inequalities for the sub-tour elimination in order to ensure the existence of a feasible solution, each time that the PSP is resolved. (Tang, Jiang, & Saharidis, 2013), in order to further narrow the solution space of the initial RMP, propose some valid inequalities for the logistics network design problem with capacity expansions of existing warehouses. These valid inequalities combine all binary variables of the RMP problem to speed up the convergence to the optimal solution by no longer generating feasibility Benders cuts. (Saharidis, Minoux, & Dallery, 2009) have developed a series of valid inequalities for the optimal scheduling of crude oil in a refinery network, where Benders decomposition was applied in order to solve large instances of the problem.

The main issue concerning the method of initializing the RMP is that the generated valid inequalities are case-study-dependent. For this

reason, (Saharidis, Boile, & Theofanis, 2011) presented a series of valid inequalities which constitutes the first attempt to generalize the previously developed valid inequalities and extend applicability to the general fixed-charged network design problem. The presented numerical examples show that the initial lower bound of RMP using the valid inequalities increased significantly compared to the classical Benders algorithm resulting to considerable reduction in the CPU time.

A contemporary and very promising approach for the warm starting of the RMP is proposed by (Naoum-Sawaya & Elhedhli, 2013). The authors present an interior-point branch-and-cut algorithm for structured integer programs based on Benders decomposition and the analytic center cutting plane method (ACCPM).

They show that the ACCPM based Benders cuts are both pareto-optimal and valid for any node of the branch-and-bound tree and are used to warm-start the solution of the nodes after branching. The proposed ACCPM-Benders-branch-and-cut algorithm (ABBC) is compared to the classical Kelley's like Benders-branch-and-cut (KBBC) algorithm and the classical Benders decomposition with and without pareto-optimal cuts. The computational results show that ABBC outperforms all other approaches.

(Fakhri & Ghatee, 2013) propose a modified Benders algorithm for solving a preemptive multi-objective mixed-integer program. In fact, the authors make certain changes on the RMP and, specifically, alter its objective function and add a certain constraint. This method seems to be very promising in terms of reducing the number of iterations needed to reach convergence.

Quality of Benders Cuts

The second issue regarding the efficiency of Benders implementation is the quality of the Benders cuts. As mentioned in the previous section, every extreme point and extreme ray of the solution space of the DSP gives a valid cut for the RMP.

The maximum number of iterations of Benders algorithm is equal to the total number of extreme points and rays of the solution space of the DSP.

Prior to the execution of the Benders algorithm, it is known that it can converge in only one iteration if all possible Benders cuts were produced from the first iteration (full master problem). However, in this case the resulting full master problem would normally be more complicating than the original problem (Saharidis, Minoux, & Ierapetritou, 2010). Moreover, if we could define in advance which of the extreme points and rays correspond to the active constraints of the final RMP, then the Benders algorithm could converge in one iteration after the addition of these Benders cuts. Although this is practically impossible, a multi-generation of cuts strategy could be developed and applied in order to approximate this technique. Thus, generating additional constraints in every iteration could improve the convergence rate of the Benders algorithm. In order to be more efficient, this type of strategy should keep a balance between the number of extra cuts generated in each iteration and the size of the resulted RMP.

(Magnanti & Wong, 1981) are the first to propose generating more than one cut in each iteration to accelerate the Benders decomposition algorithm. The proposed multi-generation of cuts procedure uses Pareto-optimal cuts added to RMP together with the classical Benders cut. A cut is defined as Pareto-optimal if no other cut dominates it. The results obtained by their approach showed a significant improvement in the convergence of the algorithm. Later, (Papadakos, 2008) proved that it is not necessary to use a core point of the RMP solution space in order to produce a Pareto cut improving the convergence rate of the algorithm.

(Tang, Jiang, & Saharidis, 2013) have developed a strategy which produces Pareto cuts with high density, covering a high number of RMP decision variables. A high density cut as defined by (Saharidis, Minoux, & Ierapetritou, 2010) is a cut which covers a large number of decision variables of the RMP problem, resulting to a better convergence behavior of the algorithm due to the

restriction of the RMP solution space towards all its directions. The idea of the new method referred to as High Density Pareto (HDP) cut generation is based on (Papadakos, 2008) result. HDP (Tang, Jiang, & Saharidis, 2013) produces an additional cut which covers a large number of RMP decision variables using one of the multi-optimal solutions generated by the dual sub-problem.

Recently, (Sherali & Lunday, 2013) proposed an algorithmic strategy that utilizes a preemptively small perturbation of the right-hand-side of the PSP to generate maximal non-dominated Benders cuts, as well as a complimentary strategy that generates an additional cut in each iteration via an alternative emphasis on decision variable weights. The suggested technique represents a fundamental improvement, as it reduces the number of linear programs to be solved in each sub-problem iteration and that it does not require the identification of a core point within the RMP.

(Rei, Cordeau, Gendreau, & Soriano, 2009) showed how Benders feasibility cuts can be strengthened or replaced by local branching constraints. The main idea behind local branching is to divide the feasible region of a problem into smaller sub-regions and find the best solution (or at least a good feasible solution) in each one of them. By applying local branching throughout the solution process, one can simultaneously improve both the lower and upper bounds of the algorithm. To assess the performance of the idea, computational experiments were performed on a series of network design problems illustrating its benefits.

(Fischetti, Salvagnin, & Zanette, 2010) propose a new Benders cut selection criterion, that leads to a more clever choice of the separated cuts, in particular when both feasibility and optimality violated cuts exist. The authors propose a unified framework that generates a single type of cut, based on the fact that the primal SP can always be reformulated as an infeasible problem, i.e., the dual SP can be transformed into an unbounded problem. The computational results show the increased efficiency of the method compared to the classical Benders algorithm.

(Saharidis, Minoux, & Ierapetritou, 2010) presented a new multi-generation cut method suitable for case studies where the Benders cuts produced are most often low density cuts. A low density cut is a cut involving a small number of decision variables of the RMP, therefore its contribution to strengthening the RMP tends to be limited. The addition of a single low density cut does not restrict significantly the solution space of the RMP, thus leading to increased number of iterations and CPU solution time. The proposed strategy uses the concept of the Covering Cut Bundle (CCB). The CCB algorithm generates in each iteration a bundle of low density cuts by an auxiliary problem using the values obtained by the solution of the last RMP. Note that, in general, a bundle of low density cuts is more desirable for acceleration of the algorithm than a cut corresponding to the sum of these low density cuts, which is a high density cut itself. The produced bundle of cuts involves more decision variables of the RMP, thus restricting its feasible solution space and leading to faster convergence of the algorithm.

In (Azad, Saharidis, Davoudpour, Malekly, & Yektamarian, 2013), the authors present a method referred to as the maximum density cut (MDC) generation, which is based on the idea to generate a cut to cover the remaining decision variables which are not covered by CCB. For this reason, the authors suggest the generation of a cuts bundle, where only a certain number of decision variables is covered and the rest are covered by the MDC method. Furthermore, in (Saharidis & Ierapetritou, 2013), the MDC method is evolved and categorized into primal-MDC and dual-MDC. Its implementation as a standalone procedure accelerates significantly the classical Benders algorithm, but is outperformed by CCB. The combination of the two methods (CCB-MDC), however, leads to faster convergence than the standalone application of any of them.

A new multi-generation cuts algorithm is presented in (Saharidis & Ierapetritou, 2010) to improve the efficiency of the Benders decomposi-

tion approach for the cases where optimality cuts are difficult to be achieved within the iterations of the algorithm. This strategy is referred to as maximum feasible sub-system (MFS) cut generation strategy. In each iteration of the Benders algorithm, whenever the PSP is infeasible, the maximum feasible sub-system of the PSP is defined relaxing the remaining infeasible constraints with minimum changes and an additional cut is generated improving the RMP's objective function. Thus, each time the Benders algorithm produces a feasibility cut, an extra MFS cut is produced. The numerical results show a significant reduction of the solution time and of the total number of iterations, confirming the efficiency of the MFS cuts.

Infeasible PSPs have lately been addressed by (Martins de Sa, de Camargo, & de Miranda, 2013), as well, who introduce a new Benders cut selection scheme. Their method is based on the idea of retrieving cost information even when infeasible PSPs have to be addressed and extends the work of (Papadakos, 2008) by selecting a suitable value for the weight λ rendering a feasibility and also a Pareto-optimal cut from the infeasible PSPs. The new scheme outperforms other modern variants of the Benders algorithm (Papadakos, 2008), (Fischetti, Salvagnin, & Zanette, 2010).

(Jenabi, Fatemi Ghomi, Torabi, & Hosseini, 2015) address the power expansion planning problem and improved the convergence of the classical Benders algorithm by proposing three groups of additional cuts and adding them to the RMP. The first set of cuts, namely *valid inequalities* (VI), restricts the RMP from first iteration improving the quality of lower bound obtained. Second set of cuts are obtained by disaggregation of classical Benders cuts leading to *multi-generation of cuts*. For the third method, *high-density cuts* (HDC) are constructed by a combination of two well-known approaches, i.e. Pareto-optimal cut and MDC generation strategies, proposed by (Magnanti & Wong, 1981) and (Azad, Saharidis, Davoudpour, Malekly, & Yektamarian, 2013), respectively. All methods are tested on computational results and it is concluded that generating a bundle of relatively

low density cuts shows better performance than generating a single high density cut.

(Verstichel, Kinable, De Causmaecker, & Vanden Berghe, 2015) propose an exact Combinatorial Benders' decomposition to the lock scheduling problem. When an infeasible subproblem is encountered, one or more Combinatorial Benders cuts are generated and added to the master problem. The experimental results show that the proposed Combinatorial Benders' decomposition is very effective for the lock scheduling problem.

Concerning stochastic programming, (You & Grossman, 2013) present a multicut version of the Benders decomposition method for solving two-stage stochastic linear programming problems, including stochastic mixed integer programs with only continuous recourse variables. The main idea is to add one cut per realization of uncertainty to the master problem in each iteration, that is, as many Benders cuts as the number of scenarios. Computational studies show that significant savings in CPU time can be achieved by using the proposed multicut algorithm. (Oliveira, Grossman, & Hamacher, 2014) address the solution of a two-stage stochastic programming model, as well, and present the development of acceleration techniques for the stochastic Benders decomposition. The authors introduce the *dynamically updated near maximal Benders cuts* to strengthen the cuts generated and two additional acceleration techniques to improve the quality of the solution obtained from the MP by using *primal heuristics* and addressing the distance between two successive solutions (*trust region*). Their method of outperforms methods described by (Papadakos, 2008) and (Sherali & Lunday, 2013). Additionally, (Keyvanshokoo, Ryan, & Kabir, 2016) address a two-stage stochastic problem and introduce a hybrid robust-stochastic approach. To solve a combinatorial problem, an accelerated stochastic Benders decomposition algorithm is proposed. Two groups of valid inequalities are added to RMP, in order to substantially improve the lower bound, and Pareto-optimal cuts (Papadakos, 2008) are also applied to further accelerate convergence. Experiments prove the efficiency of their proposed approach.

Finally, (Vatsa & Jayaswal, 2016) introduce a novel model for the multi-period maximal covering location problem with server uncertainty and apply a modified Benders decomposition for its solution. The authors suggest several refinements to the Benders method, like heuristics for the subproblem and cut strengthening methods, which drastically reduce the computational time needed to solve problem instances.

FUTURE TRENDS

In order to further accelerate the Benders decomposition, a new strategy to explore is parallel optimization, since the solution of PSP and auxiliaries' problems (for the generation of multi-cuts) could be solved at the same time as the RMP. Moreover, one could investigate the fluctuation of the upper bound (in case of minimization) and how it is related to the convergence rate of the algorithm.

CONCLUSION

In this book chapter, the Benders decomposition algorithm is presented. The main drawbacks of this decomposition algorithm are put in focus. The chapter provides all theoretical results existing in the literature which have been developed in order to overpass these issues and accelerate the convergence of the classical Benders algorithm.

KEY TERMS AND DEFINITIONS

Benders Decomposition: Benders decomposition method is a classical approach for combinatorial optimization problems, based on the idea of partition and constraint generation.

Block-Decomposed Mathematical Model: A mathematical model which can be decomposed into sub-models.

Decomposition Technique: Solution method in which the main idea is to decompose the problem into sub-problems which are simpler to be solved.

Low Density Benders Cut: A cut involving a small number of decision variables of RMP therefore with low contribution to strengthening the RMP.

Multi-Generation of Cuts: The generation of more than one constraint in each iteration of Benders algorithm.

Quality of Benders Cut: A measurement of how efficient Benders cut is, affecting the Benders algorithm convergence.

Valid Inequality: An inequality which significantly restricts the solution space of a problem without excluding the optimal solution and leading to improve the convergence of a solution approach.

Lean Logistics of the Transportation of Fresh Fruit Bunches (FFB) in the Palm Oil Industry

Cheah Cheng Teik

Universiti Sains Malaysia, Malaysia

Yudi Fernando

Universiti Malaysia Pahang, Malaysia

INTRODUCTION

Variation in the production process is the cause of quality problems, (Zylstra, 2012). This is the manner of transportation of Fresh Fruit Bunches (FFB) in the palm oil industry. It can be an awesome responsibility that only gets more difficult and complicated as the estate gets larger with more hectare and the distance from mill gets farther. Despite the long distances, time zones and other hurdles involved, it is necessary for estates to reduce cost and inventory. The FFB and loose fruits must be delivered to the mill same day it is harvested and collected. Zero inventory would definitely reduce cost and increase productivity but how to go about it is an industrial problem in this important industry. The problem all the way is not just forecast accuracy but all variability, (Zylstra, 2012). Applying lean approach to distribution would compartmentalize and reduce variability such that replenishment become much easier and planning can be more effective. The ideal model is to reduce contact (damage to FFB), reduce time to consumer (deliver FFB to mill on the day of harvest) and completely eliminate as much cost as possible (efficient and effective transport of FFB).

BACKGROUND

The second top producer of palm oil after Indonesia is Malaysia. In 2014, the planted area

is 5.39 million hectares. It has increased 3.1% against 5.23 million hectares compared to year 2013. Sabah is the largest oil palm planted state with 1.51 million hectare or 28% of total oil palm planted area. In the palm oil industry, Malaysia is successful in terms of producing and marketing the palm oil, palm kernel oil and their derivative products. There are also huge amounts of palm oil wastes generated by the industry. This included oil palm shells, mesocarp fibre and empty fruit bunches from the mills, also oil palm fronds and oil palm trunks from the field during replanting.

The oil palm is five to ten times more productive in terms of oil yield than all other oil-bearing crops. It is in the best position to meet the growing global demand for oil. It is versatile and there are demands for palm oil in the non-food sector. Oil palm also contributed in the energy sector. Its biomass and biogas can be used as fuel for boilers. Palm oil is used as feedstock to produce biodiesel by blending palm diesel with petroleum diesel. This lowers the burning of fossil fuel in the world. Statistics Malaysia Palm Oil Board (MPOB).

Misguided anti-palm oil campaigns have been a talk of the town and the burning issues in business. This has been a constant challenge for the palm oil industry. During the 1980's the campaign were on health issues and Malaysia gather international independent experts to defend it.

Today the lobbyist turned their attacks to environmental and sustainability issues and MPOB, Ministry of Plantation Industries and Commodities

(MPIC) had continued to address them. Since oil palm is grown in one of the most ecologically sensitive areas of the world, it is imperative to grow it in a sustainable manner so that people, planet and profit are all part of the equation.

Bad things can happen to good companies that fail to take a broad view of accountability, (Savitz, 2012). Certifying Malaysia Sustainable Palm Oil (MSPO) and producing Sustainable Palm Oil is important for the country's business to promote export and sales to compete in the world market.

Even a well run company with good intentions and with a proud history of business and philanthropic achievement can stumble and fall when the principles of sustainability is ignored, (Savitz, 2012). The four areas in commitment to sustainability are land use, water, climate change and farmer livelihoods. As land is finite and human population is growing rapidly, it is important to ensure that the use of land is sustainable.

For market development, MPOB provides oil palm industry players with relevant economics and statistics. The important markets for our Malaysian palm oil are China, European Union, India, Pakistan, USA and West Asian countries. Currently, 1.29 million hectares of palm plantations in Malaysia are Round Table Sustainable Palm Oil (RSPO) certified and these contribute to 4.8 million tonnes of certified sustainable palm oil, (Datuk Amar Douglas Uggah Embas, Plantation Industries and Commodities Minister, 2015).

A look at the world market which concern palm oil, Malaysia must work hard to compete with an added advantage to promote sales of our palm oil and to start with encouraging MSPO and carrying out relevant research to further improve the industry for the estate, mill and refinery. A very important area which need focus is the transportation of FFB, the raw material for palm oil mills. Along with marketing come logistics aspects, which are as important to create differentiation advantages and competitiveness of retail supply chains (Lorentz and Lounela, 2011). The brand value of a company consists of intangible assets such as reputation and customer loyalty.

Oil palm is the most important agriculture crop and palm oil industry is the pillar of Malaysian agriculture and main stay of rural economy. It is an engine of growth contributing about one-third of the agriculture Gross Domestic Product (GDP). The industry provides employment to more than 610,000 people including some 200,000 small holders. (Statistics MPOB).

MPOB has developed a sustainability certification scheme Malaysia Sustainable Palm Oil (MSPO). The government has approved this on 21st March 2014 and this scheme is officially implemented as of January 2015. This is an alternative to currently available certification schemes like International Sustainability and Carbon Certification (ISCC), Roundtable on Sustainable Biomaterials (RSB), Indonesian Sustainable Palm Oil (ISPO), and Roundtable on Sustainable Palm Oil (RSPO). Innovation is pivotal to the success of the palm oil industry. As for now, there are 9 estates, 3 independent small holders and 6 mills certified MSPO. The benefits of certification are to broaden market access with the increasing demand for sustainable palm oil. It will enhance organizational image as it is seen as social responsibility. This further facilitates access to the growing "green market". The Malaysian palm oil industry strives to strike a balance between social, environmental and economic needs of country and people.

Issues and Problems

The research gap and problem statement is found no attempt done to make transport of FFB efficient and effective, integrating lean logistics with triple bottom line to address sustainability. The existing systems ignore new competitive realities that require a strong focus on such issues as product and process quality, customer satisfaction, and cross-functional integration, (Fawcett and Cooper, 1998).

Technology is a solution for the depleting agriculture land and the need to boost production because of rise in consumption. Malaysia Palm

Oil Board (MPOB) developed superior oil palm planting material with excellent oil yield potential and the breakthrough were published in highly acclaimed journal, *Nature*. Now we have the good planting material but the problem of transporting the produce (FFB) from estate to mill remain a grey area to be seriously researched.

The performance measures in five broad areas of logistics are transportation, warehousing, inventory control, order processing and logistics administration. A performance measure consist of efficiency and effectiveness, (Mentzer, Konrad, and Ponsford, 1991). The major transportation measures are labour, cost, equipment, energy and transit time. The different vehicle types and sizes and different physical sizes of goods loaded can cause loading time variances. All these factors are important for the transportation of FFB and there must be zero inventory.

A sustainable company manages its risk and maximise its opportunities by identifying key non-financial stakeholders and engaging them in matters of mutual interest, (Savitz, 2012). They are required to have strong values, great personal integrity, and a willingness to make the tough call. There has to be openness and transparency with multiple constituents.

What motivated this study is because the world population is always in need of a steady supply of vegetable oils and fats. The efficient transportation of fresh fruit bunches (FFB) to mill has become relevance to major challenges in the field. Heavy loading of FFB vehicle is seen daily and coupled with very poor condition roads is not only unhealthy but also post danger to the community. In related efforts only some short distance roads were tar to attract FFB suppliers to send FFB to mill but do not take into consideration issues of sustainability.

The physical nature of a product substantially effects almost every expect of logistics and distribution systems. It has to do with packing materials, handling, storage and transportation. The structure and cost of a distribution system of a given product are directly affected by the

products particular characteristics of volume to weight ratio, value to weight ratio, substitutability and special characteristics, (Farahani et al. 2011). The FFB is a special product and cannot be left in the field after harvesting. It must be delivered to mill on the same day.

In brief the objectives of the research is to innovatively triangulating the FFB transport process of efficiency and effectiveness and the assessment of logistics performance.

Customer service is the output of logistics because logistics involves delivering the right product to the right customer at the right place, at the right time with the right cost and quality. Where FFB is concern, the right quality is at time of harvest, the right time is on the same day of harvest and the right place is the palm oil mill. Cost would depend on the estate manger to plan his routing well since the estate is a large area with many hectare, his logistics network design must be carefully work out to effectively reduce the distance the FFB lorry need to travel to all collection centres before reaching mill.

In brief the research questions is what is the most important scope for logistics performance to be sustainable in FFB transportation.

SIGNIFICANT OF STUDY

Transportation plays a major role and is the most important element in logistics because of its considerable cost. It accounts for between 1/3 to 2/3 of total logistics cost and is about 10 to 20% of a product price. The significance of logistics has evolved from a more passive and cost minimization oriented activity to a key success factor for firm competitiveness, (Spillan, McGinnis, George, Yi 2013). It has become an integral part of a firm's strategic planning process. Researchers argued that the global manufacturing strategies alone may not be effective if not supported by successful logistics/supply-chain management strategies. Basic logistics decisions mainly deal with physical movement of the products. It must at the same

time be created from a unique set of operational and dynamic capabilities. It is the combination of both which is a source for sustainable competitive advantage, (Eisenhardt and Martin, 2000).

UNDERLYING THEORY

An important theme of performance is that of efficiency versus effectiveness. Achabal et al. (1984) argued that efficiency deals with the allocation of resources across alternative and it is about minimizing inputs given a level of output. Effectiveness is concerned with determining the strategy to maximize revenue given a level of input. This will search for the most effective use of resources assuming resources are used efficiently, (Sheth and Sisodia, 2002). Gronroos and Ojasalo, (2004) also posit that there are two sides to performance where efficiency (the cost-effective use of resources) and effectiveness (the revenue-generating capability). In the conceptual framework lean logistics to triple bottom line shows efficiency. Triple bottom line to sustainable logistics performance shows effectiveness. This shows the two sides to performance for lean logistics to sustainable logistics performance. Continuous performance measurement matrices in terms of efficiency and effectiveness are proved to be appropriate methods for continuous evaluation of lean performance, (Govindan, Azevedo, Carvalho, Cruz-Machado, 2015).

Logistics salience positively impacts logistics innovativeness and logistics service differentiation. Logistics innovativeness and logistics service differentiation positively influence logistics performance. This is in accordance to the resource based view of the firm which states that resources lead to capabilities which leads to performance. It highlighted the importance of logistics within firms and indicated that the function must be made salient throughout the firm to further capitalize on the benefits of logistics which include

enhanced logistics capabilities and their eventual impact on logistics performance. (Ralston, Grawe, Daugherty, 2013).

RESEARCH THEORETICAL FRAMEWORK

Path 1 investigates the relationship between lean logistics and sustainable logistics performance in the transport of FFB. No studies have been conducted to relate these two constructs, the work can use different measurement variables for lean logistics and sustainable logistics performance. In the study is considered logistics challenges in transport of FFB or a lean logistics construct that could be applied in the estate environment. Therefore, a new estate measurement construct for lean logistics was developed to study its impact on sustainable logistics performance. Lean is chosen because of locality, the place is very remote and also considering the knowledge standard of the staff and workers in the estate, it is only proper to start with lean implementation.

Path 2 investigates the relationship between triple bottom line and sustainable logistics performance in transport of FFB. The study is expected to show the estates can reduce cost and increase customer service by integrating with triple bottom line functions. The study want to show there are empirical links been established between the integration of triple bottom line and sustainable logistics performance as proposed in this study's conceptual model and since there are none to-date in estate literature.

Finally, Path 3 (dotted lines) investigates the indirect effect of triple bottom line on the relationship between lean logistics and sustainable logistics performance. Estates that integrate triple bottom line in transport of FFB may enhance their lean logistics and this should result in improved logistics performance and sustainability.

Figure 2.

THE CONCEPTUAL FRAMEWORK

Literature Review

MPOB and partners identify genetic secrets to improve palm oil yield. With the identification of the VIR gene palm growers can begin to replace their nigrescens palms with the virescens variety and can eventually increase the efficiency of har-

vest and oil yield. Such advancements to enable increased yields on existing planted areas can help increase the sustainability of palm cultivation by reducing pressure on valuable tropical forest.

The integration of corporate social responsibility and sustainability principles in logistics, (Miao, Cai and Xu 2012), pay special attention on the environmental pillar of sustainability for pollution or fuel consumption. Therefore logis-

tics transport traditionally operating on very low profit margins, can consider initiatives aimed at reduction of environmental and social impacts as a means of improving their economic performance, (Maja, Piecyk and Björklund 2015). This is the case of lorry and other vehicle transporting FFB as can be seen from the pictures at appendix.

Transportation is the absolute means to transfer products and the basic concept of lean philosophy is waste. The distribution function is responsible for successful customer service and is at the same time under pressure to reduce cost and inventory, (Zylstra, 2012).

Modern logistics has more to do than just management of transport and storage of physical goods. They have been extended to the coordination of all phases identified in the course of supply, production and sale of a company and its relations with the rest of the environment in which it operates, (Pulina and Timpanaro, 2012).

Policymakers has globally recognized that the logistics sector is a key pillar for development, (Arvis, Saslavsky, Ojala, Shepherd, Busch, Raj, 2014). In economic growth and competitiveness it is therefore necessary to improve on logistics performance and to make it sustainable. Logistics performance refers to cost, time, and complexity in accomplishing import and export activities and is statistically significantly related to the volume of bilateral trade. (Hausman, Lee, Subramanian 2013).

We measure everything move or not move because it still cost us to deal with it, (Bowersox et al. 1995). The palm estates cannot afford the FFB to seat. The FFB and loose fruits must be collected and send to mill the same day of harvest. The cross-functional nature of logistics makes it vital to every corporate strategy, particularly to actions and policies aimed at ensuring environmental and social sustainability of operations, (Maja et. al. 2015). Logistical capabilities at the company level play a key role in integrating global supply chains, (Wiengarten, Pagell, Ahmed, Gimenez 2014). In the palm estates there is a need to innovate

efficiency and effectiveness for transportation of FFB and to address sustainability.

The TBL dimensions are commonly known as the 3Ps which is profit, planet and people. It is necessary to define and measure the sales growth, cost efficiency, profitability, high yields, flexible for change in economics to address sustainability and logistics performance. Logistics plays a key role for industries and reveals a critical function designed and managed to pursue economic goals. (Digiesi, Mossa, Mummolo 2012).

Logistics service providers pursued environmental objectives by involving customers in their operations to perform logistics activities and achieve environmental performance, (Lun, Lai, Wong, Cheng 2015). It is in the logistic operations where most organizations can and do implement green supply chain strategies, (Byrne, Ryan, Heavey 2013).

Environmental performance of logistics is often consistent with the bottom-line impacts. LSPs traditionally operating on very low profit margins, can consider initiatives aimed at reduction of environmental and social impacts as a means of improving their economic performance, (Maja et. al. 2015),

Quality and production logistics have traditionally been investigated using independent approaches. Contributions have focused on their mutual inter-relation showing that benefits can be achieved from an integrated analysis. (Cagliano, Mustafa, Rafele, Zenezini 2014).

Awareness of integration's competitive potential is insufficient to mobilize resources and mitigate resistance to collaboration. Commitment is a super ordinate enabler, (Henry Jin, Fawcett, Fawcett 2013). Integrating sustainability into firms requires action that exceeds organizational boundaries. (Seuring, Gold 2013).

A determinant of logistics performance is the supply chain alignment. Leadership has partial mediation effect between supply chain alignment and human performance, (Dubey, Singh, Gupta 2015). The demands and expectations of

stakeholders must be an input for implementing sustainable practices, (Golicic and Smith, 2013).

Peter Oberhofer and Maria Dieplinger (2014), defined sustainability in a broad sense including social, ecological and economic aspects aiming at a viable integration of a company in the long run.

The dimensions of sustainability are economic prosperity, environmental stewardship and social responsibility or profit, planet and people, (Willard, B. 2012). In practicing sustainability, companies can increase shareholder value by properly managing risk, anticipating regulatory action and processing new markets, (Savitz, A. 2012). To meet today's and tomorrow's societal sustainability challenges, (Quist and Tukker 2013), pointed out that sustainable innovation, learning and collaboration are inherently interlinked and therefore all must be integrated with a long term focus upon sustainable societal transformation which will require behavioural, cultural and structural changes to society. A fully sustainable supply chain will develop a practical approach towards sustainability supply chain performance measurement and management, the vein of improving supply chains and increasing recycling, (Schaltegger, Burritt 2014). Environmental sustainability has become a concern that develop initiatives towards environmental sustainability with a focus on companies involved in logistics and transportation processes, (Colicchia, Marchet, Melacini, Perotti 2013).

SOLUTIONS AND RECOMMENDATIONS

The reasons are discussed as to why it is important for lean logistics to integrate with triple bottom line and address sustainability. Based on a review of the site visits, transportation of FFB from estate to mill is an area of logistics performance where lean must be implemented. Some recommendations for the successful implementation of lean in the logistics performance of value chains are provided. Such practice will increase OER (Oil

Extraction Rate) and align with MSPO certification to enhance the country's CPO sales.

IMPLICATIONS ON FUTURE RESEARCH DIRECTIONS

Logistics Industry Trends in the years to come is reckoned to strengthen further by factors facilitating the effective functioning of the industry itself, integration, confederation, technology, legislation and globalization. Ehrhart (2013), has argued that the future logistics model company should change towards sustainable innovations which would create business opportunities. Much more search is required for a better insight into the existing strengths of logistics clusters.

No identified study has explored lean logistics and triple bottom line on sustainable logistics performance for transportation of FFB in the palm oil industry. This paper is the first of its kind which determines the state of sustainability within the field of logistics performance and identifies areas and sets the agenda for future research in this field. This paper takes a novel approach to look at the "Lean logistics and Triple Bottom Line" from the Sustainable Logistics Performance perspective by proposing a preliminary research model based on existing site conditions and empirical data. Future research direction to better the transportation must take into consideration locality.

CONCLUSION

To survive today's businesses, it must be steered through a transition from an old and dangerously dysfunctional model to a far better one that will operate in harmony with nature that strive in a carbon contained world and put down the threats of global climate disruption, species extinction, resource depletion and environmental degradation. Required to develop business model that is sustainable, (Ray Anderson, confessions of a radical industrialist). The transportation of Fresh Fruit

Bunches (FFB) in the palm oil industry required this transition to become modern in implementing lean logistics and integrating with triple bottom line to address sustainability.

The contributions of this paper include

1. Innovatively triangulating the FFB transport process of efficiency and effectiveness and the assessment of logistics performance.
2. Implementing lean logistics to investigate factors that affect logistics performance
3. Integrating with triple bottom line to address sustainable decision making.
4. As a result, management could use the managerial decision-making matrix to improve strategies.

KEY TERMS AND DEFINITIONS

Effectiveness: It is the degree to which objectives are achieved and the extent to which targeted problems are solved and is determined without reference to costs. Effectiveness means “doing the right thing” to address sustainability.

Efficiency: It is a measurable concept that can be determined by determining the ratio of useful output to total input. It minimizes the waste of resources such as loose fruits collection, energy and time, while successfully achieving the desired output. Efficiency means “doing things right”.

Fresh Fruit Bunches (FFB): It is the raw material for palm oil mills. The oil palm tree (*Elaeis guineensis*) originates from West Africa and was developed into an agricultural crop in Malaysia. The fruit from the tree is processed and has two main products crude palm oil and palm kernel.

Lean: This is zero inventory on FFB and loose fruits. The core idea is to maximize FFB value while minimizing waste. It means creating more value for mills with fewer resources.

Logistics: This is the routing network for transportation of FFB in the estates. Logistics is the management of the flow of FFB between the estate and the mill in order to meet.

OER: This is the Oil Extraction Rate. The extraction efficiency is affected by the percentage of oil content in FFB at the time of harvest. It is the amount of oil the mill can extract from it's process to the 100 tonne of the FFB being processed.

Performance: This is the efficient and effective means to address sustainability. The accomplishment of sustainable logistics performance measured against preset known standards of lean logistics and triple bottom line.

Sustainable: In transporting FFB it must have minimal negative impact on the global or local environment, community, society, and economy. It must have green and triple bottom line concept.

Transportation: This is the absolute means to transfer products of FFB. The act of taking the FFB from estate to mill through land and water.

Triple Bottom Line: The dimensions are profit, planet and people. 3BL is an accounting framework with three parts: social, environmental (or ecological) and financial. Lean logistics is integrated with 3BL in a framework to evaluate their performance in a broader perspective to create greater business value in addressing sustainability.

Major Techniques and Current Developments of Supply Chain Process Modelling

INTRODUCTION

While there are many definitions of supply chains, a supply chain can be defined as a set of inter-linked business processes that add value from the perspective of end customers in terms of products and/or services (Christopher, 2011). Value to the customer includes good quality, a fair price and fast and accurate (i.e., correct items in full quantity on time) delivery (Russell & Taylor, 2014). This means that a supply chain can be regarded as an overarching business process which covers a full range of activities from raw material supply, manufacturing of components and finished products, to distribution of the finished products to end customers (Russell & Taylor, 2014). In other words, a supply chain is an extended process covering all activities from the point of origin to the point of consumption. Supply chain process modelling (SCPM) is essential for understanding, design or reengineering of a supply chain (Borstorff & Rosenbaum, 2012). Meanwhile, SCPM presents many challenges due to a large number of companies involved in the supply chain and the complexity in communication and interactions between them (Brown, Recker & West, 2011).

In this chapter, we first offer some background information on supply chain processes and SCPM. Then this is followed by critical discussion of the frequently used standards/techniques for SCPM. Finally, the chapter is concluded with discussion of future trends and research directions.

BACKGROUND

Supply chain management (SCM) has received increasing attention in the literature since the early 80's (Ellram & Cooper, 2014). While there are many definitions of SCM, it can be defined as the integration of key business processes covering a wide range of activities from the original supplier to the end customer that add value to stakeholders in terms of products, services and information (Cooper, Lambert, & Pagh, 1997; Mentzer et al., 2001). Many researchers support this process view of the supply chain and argue that it helps to reduce supply chain costs and enhance customer satisfaction (Trkman, Stemberger, Jaklic, & Groznik, 2007).

There are a number of models or frameworks for a holistic understanding of supply chain processes (Ellram & Cooper, 2014). The supply chain operations reference (SCOR) model developed by the Supply Chain Council (SCC) identifies six core processes in a supply chain: plan, source, make, deliver, return and enable (SCC, 2012). Meanwhile, the Global Supply Chain Forum (GSCF) pinpoints eight key business processes in a supply chain that work at both the strategic and operational levels for the improvement of internal and external results (Croxtton, Garcia-Dastugue, Lambert, & Rogers, 2001). Recently, Xu, Koh, and Parker (2009) propose a research framework that consists of seven business processes for manufacturing coordination in a complex supply network.

DOI: 10.4018/978-1-5225-2255-3.ch472

Though these supply chain models or frameworks have different purposes and scopes, the business processes proposed in these models or frameworks need to be analysed and implemented in practice through modelling.

Clearly, SCPM is closely related to business process modelling (BPM) as a supply chain process can be viewed an extended business process. BPM is often used as a platform for achieving a common understanding of a business process (Aguilar-Saven, 2004). It has been broadly recognised that good process models are essential for business process re-engineering (BPR) (or improvement) or for information system development. Generally, BPM can be regarded as a methodology which employs software systems to analyse, design and improve business processes so that a company's business performance in terms of productivity and profits can be improved (Bae & Seo, 2007; Trkman et al., 2007).

In the body of literature on BPM, it is a common view that depending on the purpose of modelling, one should choose an appropriate technique for a particular modelling task (Aguilar-Saven, 2004). This is because there are many tools and techniques currently available in the market from basic tools (e.g. flowcharting) to more complex techniques (e.g., Petri Nets) (Recker, Rosemann, Indulska, & Green, 2009). Generally, the techniques commonly used for BPM can be categorised into two classes: (1) descriptive (or pragmatic) approaches (e.g., the SCOR model), and (2) formal (or rigorous) approaches (e.g., simulation) (Aguilar-Saven, 2004; Ryan & Heavey, 2006). As a supply chain usually consists of a number of business processes, many techniques for BPM can be used for SCPM.

Though BPM can be regarded as the predecessor of SCPM, it poses more challenges than traditional BPM. This is because a supply chain is often a boundary-spanning process that includes at least a company's immediate suppliers and customers. Therefore, it is important to have a holistic view of the overall supply chain process, including inbound logistics, internal operations and outbound logistics (Min & Zhou, 2002). The

SCOR model is best known for modelling an overall supply chain in a structured and hierarchical way (Kasi, 2005).

MAIN FOCUS

Currently there are a wide variety of standards and techniques for SCPM. Leading standards such as SCOR and unified modelling language (UML) have been well recognized and adopted by researchers, practitioners and system developers for BPM and/or SCPM. In this chapter, we focus on those techniques that have been most frequently adopted for SCPM. Specifically, we will focus on four descriptive approaches (i.e. SCOR, IDEF, UML and BPMN) and two formal approaches (i.e. Petri Nets and simulation) for SCPM.

Descriptive Approaches

Supply Chain Operations Reference Model (SCOR)

SCC released the SCOR 1.0 model in 1996 that can be used to describe supply chain operational processes for the purposes of (re)-design, (re)-engineering or improvement. The SCOR model is broadly recognised as the first cross-industry framework that can be used to measure, evaluate and improve supply chain performance. As a reference model, SCOR provides a standardized terminology and a glossary of indicators chain members can use to achieve a common understanding of supply chain processes and to evaluate their performance (Persson, 2011). By comparing the current versus the future state of a process, SCOR empowers BPR. It also allows a company to benchmark their processes against best performers' processes in the industry and to apply best practices for specific business processes. In summary, the SCOR model is built on the three important mechanisms for improving business performance: reengineering, benchmarking and best practices (Lambert, Garcia-Dastugue, & Croxton, 2005).

Table 1. Three levels of process details in the SCOR model (source: SCC, 2012)

	Level		Examples	Comments
	#	Description		
Within scope of SCOR	1	Process Types (Scope)	Plan, Source, Make, Deliver, Return and Enable	Level-1 defines scope and content of a supply chain. At level-1 the basis-of-competition performance targets for a supply chain are set.
	2	Process Categories (Configuration)	Make-to-Stock, Make-to- Order, Engineer-to-Order Defective Products, MRO Products, Excess Products	Level-2 defines the operations strategy. At level-2 the process capabilities for a supply chain are set. (Make-to-Stock, Make-to-Order)
	3	Process Elements (Steps)	- Schedule Deliveries - Receive Product - Verify Product - Transfer Product - Authorize Payment	Level-3 defines the configuration of individual processes. At level-3 the ability to execute is set. At level-3 the focus is on the right: - Processes - Inputs and Outputs - Process performance - Practices - Technology capabilities - Skills of staff
Not in scope	4	Activities (Implementation)	Industry-, company-, location- and/or technology specific steps	Level-4 describes the activities performed within the supply chain. Companies implement industry-, company-, and/or location-specific processes and practices to achieve required performance

SCOR classifies a supply chain process into four hierarchical levels: process types, process categories, process elements and implementations as illustrated in Figure 1. Note that the implementation level is outside of the current scope of SCOR and thus is not covered by it. Level 1

defines the business scope and sets performance targets through the use of six basic processes: plan, source, make, deliver, return and enable (as shown in Figure 1). Level 2 decomposes the first five basic processes into 26 process categories, and each is labelled as planning, or execution or

Figure 1. Six major management processes in the SCOR model (source: SCC, 2012)

enabling. By choosing from these core process categories, a company can configure its own SCOR model. Level 3 identifies the specific process elements such as scheduling and production within a given configuration.

In brief, SCOR enables detailed analysis of a company's processes at three levels: Level 1 defines the business scope; Level 2 configures the supply chain; and Level 3 provides the detailed process elements and performance attributes (Li, Su, & Chen, 2011). The latest 11th version of the SCOR model provides greater guidance to supply chain managers with regards to the enabling processes, best practices and cost metrics such that they better manage data, assets, networks and performance (SCC, 2012). Thus, SCOR is considered by many practitioners and researchers as a 'supply chain excellence' approach for enhancing a company's competitive advantage (Bolstorff & Rosenbaum, 2012).

Nevertheless, SCOR has a number of limitations. First, the *return* process cannot be applied to the service industry directly as return of a service does not make business sense (Barnard & Mollaghasemi, 2006). Second, though SCOR is an excellent tool for assessing supply chain performance, it does not have the capability for solving problems (Husby & Swartwood, 2011). Third, managers tend to adopt SCOR at the high level but fail to implement it at a more detailed level (Husby & Swartwood, 2011). Finally, SCOR poses some special challenges with respect to its implementation in developing countries due to such constraints as shortage of qualified employees and inexperience of people in using new or sophisticated technologies (Georgise, Thoben, & Seifert, 2011).

Unified Modelling Language (UML)

Unified modelling language (UML) was used as a standard by the Object Management Group (OMG) in 1997, and has been managed by OMG since then. The current version of UML (i.e., v2.5) was officially released by OMG in June 2015. The

popularity of UML is evidenced by its international status as the ISO/IEC 19501:2005 standard (ISO, 2016). In practice, UML has become one of the most frequently adopted standards for modelling object-oriented information systems in the software industry (Xu, 2010).

UML's notations are derived from three object-oriented methods: object modelling technique (OMT), object-oriented software engineering (OOSE), and Booch method. A key feature of UML is that it enables multiple views (e.g., static vs. dynamic view) of the process or system that is modelled (Stefanovic & Stefanovic, 2008). UML v2.5 defines 14 official diagrams which include activity diagram, object diagram, use case diagram, sequence diagram, etc. These diagrams can be classified into two categories: structural (i.e., the components of a system), and behavioural (i.e., how a system evolves over time or reacts to changes) (Stefanovic & Stefanovic, 2008). For instance, software developers often use sequence diagram to present the interactions between enterprise information systems and users in a time sequence (Xu, 2010).

In summary, UML can be used to specify, visualize and document business processes for BPR or information system development (Rumbaugh, Jacobson, & Booch, 1999). It has achieved success in modelling large and complex systems by using an engineering-based approach (Aguilar-Saven, 2004). Nevertheless, UML has certain weaknesses. Ryu and Yucsan (2007) suggest that UML lacks the ability to describe dynamic and collaborative processes where multiple participants are involved. Another shortcoming of UML is lack of formality needed for simulation and quantitative analysis (Baresi, 2001). To counter these weaknesses, UML has been used with other methods such as IDEF and the more formal approach of Petri Nets (Ruy & Yucsan, 2007).

The IDEF Family

IDEF was originally from the integrated computer-aided manufacturing (ICAM) project which was

Figure 2. Hierarchical structure of IDEF0 modelling approach

carried out by the US Air Force in the mid-1970s (Aguilar-Saven, 2004). IDEF denotes 16 modelling tools from IDEF0 to IDEF14 plus IDEF1X that can be used for system analysis and process design. IDEF0 defines the activities and their requirements in a system or organization. In alignment with the top-down design approach, IDEF0 uses a hierarchical approach for functional decomposition as illustrated in Figure 2.

The model starts by representing the whole system as a single box at the highest level labelled A0. The A0 box can be decomposed into a set of activities at level A1. This process repeats until the system is described in the necessary detail. In this hierarchical structure, each activity (or process step) is represented as a box. Inputs are information and/or materials which are transformed by the activity to outputs. Controls are the information and/or materials used to constrain the activity. Resources are people, facilities or systems that perform or provide the energy to the activity. From the user's perspective, IDEF0 uses simple rules and visual vocabulary for describing a system or business processes, making it easy to learn and visually appealing.

Among these 15 notations (IDEF0 – IDEF14 plus IDEF1X), IDEF0 is the most popular one on the market for a number of reasons. First, IDEF0 is visually appealing to users with its easy-to-understand vocabulary for description of a business process or system. Second, IDEF0 has simple yet strict rules making it easy to learn and understand. Furthermore, IDEF0's functional decomposition provides process views at both macro and micro levels of an organization. This makes it suitable for analysis of business processes in a supply chain system (Xu, 2015). Meanwhile, IDEF3 is also popular for BPM or SCPM as it provides the basis for process modelling. Nonetheless, IDEF0 and IDEF3 have different focuses on BPM. IDEF0, often called 'functional modelling', defines the activities that need to be conducted in a process, while IDEF3, known as 'process modelling', depicts how a process works (Ryu & Yucesan, 2007).

Nonetheless, both IDEF0 and IDEF3 have limitations. For example, people tend to interpret IDEF0 models as a series of activities since they may be presented as "boxes" in a left-to-right sequence (Aguilar-Saven, 2004). IDEF3 is ap-

propriate for delineating a static process but has limitations for describing a dynamic process (Ryu & Yucesan, 2007). Also, IDEF3 has limitations in terms of tracking all participants involved in a collaboration process. This limitation of IDEF3 renders it unsuitable for modelling collaborative business processes in a supply chain context where chain members interact dynamically with each other over time (Ryu & Yucesan, 2007).

Business Process Modelling and Notation (BPMN)

Business process management initiative (BPMI) released the first version of business process modelling and notation (i.e., BPMN v1.0) in 2004. Since BPMI and Object Management Group (OMG) merged in 2005, BPMN has been maintained by OMG. Hence BPMN is the latest member in the family of BPM tools. BPMN aims to provide a notation that is readily understandable by the business analysts creating the initial drafts, the technical developers responsible for implementing those processes, and all the business users managing and monitoring the processes (White, 2006). To this end, BPMN constructs are differentiated into two sets: a set of core graphical elements and an extended set of specialised elements (Recker, 2011). The core set was designed as a basic notation that is used to describe the essence of business processes, while the extended set supports complex process scenarios such as workflow specification (Recker, 2010).

BPMN has evolved significantly since its inception in 2004 as a graphical enrichment to the formal approach of UML (Dumas, La Rosa, Mendling, Reijers, 2013). As the latest version of BPMN, v2.0 was released by OMG in 2011. Enhancement of BPMN's functionality has been focused on quality (Moreno-Montes de Oca, Snoeck, Reijers, & Rodriguez-Morffi, 2015), process tailoring (Pillat, Oliveira, Alencar, & Cowan, 2015) and time (Arevalo, Escalona, Ramos, & Dominguez-Munoz, 2016). In its current version, BPMN defines five types of

modelling elements: flow objects, connecting objects, data objects, swimlanes and artifacts (OMG, 2011). Flow objects (e.g., activities) are the basic elements for creating BPMN models. Connecting objects are used for connecting flow objects through various types of arrows. Data objects show how data or documents are used and updated during the process flow. Swimlanes are used to group activities into categories for differentiating functional responsibilities. Artifacts can be added to a BPMN model to illustrate related information such as processed data. For further information on BPMN v2.0, reader can refer to OMG (2011).

Since its first release, BPMN has quickly attracted attention from practitioners and academics (Recker, 2010). To a large extent, BPMN can be considered as the de facto standard for BPM (Recker, 2010; Yousfi, Bauer, Saidi, & Dey, 2016). Nonetheless, BPMN has a number of deficits. Particularly, BPMN does not provide sufficient support for users to specify business rules in their BPMN models (Recker, 2010). Similarly, BPMN has inadequate support for capturing process decomposition (Recker, 2011). This deficiency makes BPMN unsuitable for modelling of complex supply networks where process decomposition is essential for analysis of supply chain processes at different levels.

Formal Approaches

Petri Nets

Petri Nets was named after Dr. Carl Adam Petri who was credited as the developer of this modelling technique in the 1960s (Wang, 2007). Its main strength lies in its ability of combining graphical representations of system dynamics with mathematical analysis (David & Alla, 1994). Petri Nets can be used to describe and analyse concurrent systems where many entities (e.g. people) share the same resource (e.g. aeroplane). A classic Petri Net comprises two types of nodes as shown in Figure 4:

Figure 3. An example of Petri Net (Peterson, 1981)

1. 'Places' (graphically represented by circles,
2. And 'transitions' (graphically represented by bars).

Places (circles) and transitions (bars) are connected by 'input arcs' (from a place to a transition) and 'output arcs' (from a transition to a place). Figure 3 illustrates an example of Petri Nets.

According to the literature, a classic Petri Net has some drawbacks. First, it lacks data concepts which often results in oversized models. Second, a classic Petri Net lacks hierarchy concepts, which makes it unsuitable for building a large model (Aguilar-Saven, 2004). Therefore, a classic Petri Nets is unable to model complex, high-level business processes (Leymann & Altenhuber, 1994). As a result, classic Petri Nets have been extended in three aspects (i.e., time, colour and hierarchy) to enhance their capabilities. These extensions are often referred to as high-level Petri Nets (van der Aalst & van Hee, 1996).

To overcome the drawbacks of classic Petri Nets as mentioned above, coloured Petri Nets (CPNs) incorporates both data structuring and hierarchical decomposition into classic Petri Nets without compromising qualities of the original Petri Nets (Ramadan, Elmongui, & Hassan, 2011). These characteristics of CPNs make them suitable for modelling large complex systems such as supply chain networks that have a number of business processes (Aguilar-Saven,

2004; Landeghem & Bobeanu, 2002). Among the various versions of Petri Nets, CPNs are most well-known to researchers in the field of BPM or SCPM (Ramadan et al., 2011). Nevertheless, CPNs still have limitations in modelling collaborative business processes. Though coloured tokens can be used to differentiate various participants, the complexity of a model will increase significantly when a new participant is added to the existing model (Ryu & Yucesan, 2007).

Simulation

Like UML, simulation is another engineering-based technique for modelling. It is one of the most popular modelling techniques in operation management (Pannirselvam, Ferguson, Ash, & Siferd, 1999). There are two reasons for the popularity of simulation. First, analytical approaches (e.g., mathematical equations) tend to be inadequate in modelling complex systems (e.g., manufacturing systems) or business processes (e.g., supply networks). Second, complex systems such as flexible manufacturing systems need to be modelled and evaluated early at the design stage such that design parameters (e.g., the number of pallets) can be optimised for a given design scenario. Often simulation is used for evaluation of a complex system with low costs prior to the actual implementation of the system.

As can be seen above, the main purpose of simulation is to obtain knowledge about the behaviour and performance of a real-world system in a cost-efficient way (Maria, 1997). By using the simulation results of a system, it is expected that management can make informed decisions with respect to design or operation of the system under assessment. To achieve this, it is essential to build a simulation model that has an adequate level of similarity to the real-world system such that the simulation results can be trusted as true representations of the real system (Giaglis, 2001).

There are various forms of simulation such as discrete-event simulation (DES), system dynamics, Monte Carlo simulation, etc. Recent studies indicate that DES is still the most popular type of simulation in practical applications (Jahangirian, Eldabi, Naseer, Stergioulas, & Young, 2010). The main purpose of DES is to understand the behaviour of a system or evaluate different design or execution strategies of the system with the constraints imposed by a set of criteria. To this end, it is essential to design a model of the system under assessment and experiment with the built model (Shannon, 1975). As supply chain processes are usually treated as discrete-event systems, DES is one of the popular tools for SCPM (Ryan & Heavey, 2006). Nevertheless, DES has weakness in stakeholder engagement mainly due to the time and efforts required for data collection (Jahangirian et al., 2010).

Compared with analytical modelling approaches such as queuing theory, simulation is much more capable in terms of mapping complex business systems (Thierry, Bel, & Thomas, 2010). In some circumstances, simulation is the only practical modelling approach that can be used to study the behaviour of real complex systems such as supply networks (Stefanovic & Stefanovic, 2008). Yet, often there are some important issues that need to be addressed when the simulation approach is chosen for system evaluation. For example, for a large complex system, one of the key issues is how to verify and validate the simulation model of the system (Maria, 1997).

FUTURE TRENDS

The leading modelling standards discussed in this chapter (i.e., SCOR model, IDEF, UML and BPMN) are well recognized and adopted by practitioners and researchers. Among them, BPMN has gained a quickly rising popularity as the de facto standard for BPM (ISO/IEC 19510:2013) since it has been widely supported by commercial modelling tools (e.g., IBM Websphere) and integrated into universities' curriculum (Recker, 2010; Arevalo et al., 2016).

To make BPMN more applicable and powerful in functionality, OMG has developed some other notations which are complementary with BPMN. For example, the decision model notation (DMN) is developed to complement BPMN in an XML representation and to create a standardized means to automate decisions in processes (OMG, 2016). Besides, the case management model notation (CMMN) can be used to incorporate knowledge workers decisions into a process's meta-model (OMG, 2016).

On the other hand, BPMN has some major drawbacks. As mentioned earlier, BPMN has limited support for process decomposition that is vital for modelling large-scale business processes such as supply networks (Recker, 2010). Further, the current version of BPMN (v2.0) does not support ubiquitous computing where one person operates multiple computers (Yousfi et al., 2016). Therefore, it is anticipated that BPMN will be enhanced or extended to overcome those limitations in the future.

From the SCM perspective, the main objective of SCPM is to assist integration and collaboration of business processes both within individual chain members and across their boundaries. To this end, the literature shows that there is an increasing trend of combining different modelling techniques that complement each other (Stefanovic, Stefanovic, & Radenkovic, 2009). For example, Ryu & Yukesan (2007) developed a new modelling method called collaborative process modelling (CPM). This new method combines the analytical power of Petri

Nets, the simplicity of IDEF3 and the representation capability of UML.

Furthermore, recent literature review shows that researchers tend to use a hybrid modelling approach for simulation where two or more techniques are used in an integrated way (Jahangirian et al., 2010). For instance, Stefanovic et al. (2009) proposed a methodology for modelling structure and dynamics of complex supply networks by combining DES and SCOR. Another line of promising research is to create a merged model that subsumes a collection of process models (La Rosa, Dumas, Uba, & Dijkman, 2013).

CONCLUSION

Though supply chains can be generally regarded as business processes, they are much broader than normal business processes as they are boundary-spanning processes from raw materials, to component/part manufacturing, assembly, the distribution channel and to retail involving many participants. From the process perspective, the SCOR model is the most comprehensive standard for SCPM as it covers major processes, metrics, inputs, outputs and best practices. Meanwhile, to overcome the complexity of supply networks (e.g., in the aerospace or automotive industry), computer simulation (particularly DES) can be used as a valuable tool to analyse and evaluate the supply networks in terms of process design, operations or improvement in a quantitative way.

Based on an extensive review of the relevant literature on BPM and SCPM, this chapter offers a summarized description and critical discussion of the prominent standards and techniques for SCPM, including SCOR, IDEF, UML, BPMN, Petri Nets and simulation. It is expected that these standards or modelling techniques will evolve over time and will become more supportive to SCPM in the future. After all, the main objective of SCPM is to promote process integration and collaboration both within individual companies and between business partners along the supply chain.

KEY TERMS AND DEFINITIONS

Benchmarking: A performance management practice by which a company compares its own business processes and performance metrics to those of the best in the industry.

Business Process Modelling: The activity of representing a company's business processes so that the current process can be performed in a more effective and/or efficient way leading to improved business performance.

Business Process Reengineering: A method by which business performance can be dramatically improved through rethinking and redesign of processes.

External Processes: The business processes that cannot be executed without involvement of an external business partner such as the customer relationship management process.

Internal Processes: The business processes that can be executed without involvement of an external business partner such as the internal production process.

Monte Carlo Simulation: A computerized simulation technique which is usually used for analyzing the behaviour of a system or a process involving uncertainties.

Object-Oriented: System design or analysis, or software program that use objects.

Process Integration: An approach of attaining close alignment and seamless coordination of internal and/or external business processes.

System Dynamics: A method through which the dynamic behaviour of a complex system over time can be better understood by taking into account internal feedback and time delays.

Measuring Low Carbon Supply Chain

Muhammad Shabir Shaharudin
Universiti Sains Malaysia, Malaysia

Yudi Fernando
Universiti Malaysia Pahang, Malaysia

INTRODUCTION

Environmental management is an important issue that has attract numerous scholars and practitioners especially the issue of climate change. Recently, scholars and practitioners are concerned with raising greenhouse gasses (GHGs) especially carbon emission and its impact on climate change (Palak, Eksioğlu, & Geunes, 2014). GHGs are dangerous but the world governments have taken initiative to control the release and used of these gasses except Carbon Dioxide. Carbon emissions are not specifically produce by manufacturer but almost by all activities. Thus, climate change mitigation strategy, which carbon emission as the main threat has been regard as very important. The mitigation strategy includes carbon taxes, carbon trading, clean development and joint implementation that can be found in Kyoto Protocol mechanism. The mitigation strategies for carbon emissions are adopted by government by introducing government regulation (Choudhary, Sarkar, Settur, & Tiwari, 2015). On the other hand, firms also need to adhere to government regulation and adopting carbon reduction strategies to meet their customer requirements and to remain competitive (Seuring, 2013). To do so, firms are expected to increase their competitiveness through Low Carbon Supply Chain Management (LCSCM) by practicing Carbon Footprint (CF). The definition of CF is the recording of carbon emissions throughout the life cycle of a product (Wiedmann & Minx, 2007).

In order to record carbon emissions, the concept of LCSCM need to be understood. As proposed

by Böttcher & Müller (2015), LCSCM consists of three groups of practices. The first is development of low carbon products in all product development process by assessing and reducing carbon emissions as well as achieving eco-design. The second practice is low carbon production process where monitoring and reduction of carbon emissions should apply in all production process until the final goods. The third practice focuses on low carbon logistics because transportation activities contribute significantly to increasing of carbon emissions. These practices are helping firms to develop carbon mitigation strategy and choose the best strategy to be implemented. As a result, firms now are able to identify and measure carbon emissions at operational and management settings.

BACKGROUND

As LCSCM is recently growing in importance, scholars and practitioners have started to put more interest in measuring carbon emission. In the literature, there are many scholars focusing on carbon emission measurement methods but lack of empirical data (Lee, 2011). Scholars then shift their focus in developing measurement methods and model to help practitioners to record and measure their carbon emissions using data generation (Bai, Sarkis, Wei, & Koh, 2012; Schmidt, 2009). However, there are also a few studies done by scholars using real firm or industrial data (Burnett, 2011; Cadarso, Gómez, López, & Tobarra, 2016; Lee, 2012; Nakajima, Kimura, & Wagner,

2014; Palak et al., 2014; Pelletier, Ibarburu, & Xin, 2013; Rahman & Khondaker, 2012; Tsai, Lin, Hwang, & Huang, 2014; Yusuf et al., 2013; Zhao, Neighbour, Han, McGuire, & Deutz, 2012; Zubelzu & Álvarez, 2015). Yet, the difficulty to get real data have seen many scholars using qualitative studies to measure LCSCM (Dadhich, Genovese, Kumar, & Acquaye, 2014; Dayaratne & Gunawardana, 2015; Gopalakrishnan, Yusuf, Musa, Abubakar, & Ambursa, 2012; Lee, 2012; Pueyo, 2013).

Difficulties in getting data also complicates the study of LCSCM. For example, in the study of Bai et al. (2012), environmental performance measurement does not give any information that can be implemented by practitioners. Another important gap in the literature is that scholars are divided between management and engineering focus when measuring LCSCM. There are a few scholars in management focus where their interest of studies are contributing to top management firm, policymakers' regulation and using management theories (de Sousa Jabbour, Jabbour, Latan, Teixeira, & de Oliveira, 2015; Fernando, Shaharudin, & Wahid, 2016; Gunasekaran & Spalanzani, 2012; Jabbour, Neto, Gobbo, de Souza Ribeiro, & de Sousa Jabbour, 2015; Lee, 2011; Matthews, Hendrickson, & Weber, 2008; Sarkis, Zhu, & Lai, 2011; Seuring, 2013; Shaharudin & Fernando, 2015; Zhu, Sarkis, & Lai, 2013). On the other hand, engineering focus scholars measure LCSCM using engineering theories such as Game Theory (Zhao et al., 2012), Chaos Theory (Stapleton, Hanna, & Ross, 2006), Swift Even Flow Theory (Seuring, 2009), Graph Theory (Wagner & Neshat, 2010), Neo-Institutional Theory (Genus & Mafakheri, 2014) and Fuzzy Set Theory (Erol, Sencer, & Sari, 2011; Liu, Perng, & Ho, 2013; Wang, Chan, Yee, & Diaz-Rainey, 2012) to name a few. This chapter is interested in looking at previous studies on LCSCM on management focus as it provides rich information to both scholars and practitioners.

The objectives of this study is twofold: 1) outcome of LCSCM and 2) measurement of LCSCM.

The significance of the study is that this chapter is contributing to LCSCM management focus literature. In model development, through extensive literature review, this chapter will provide evidence that LCSCM is an outcome that firms are pursuing. On the other hand, the literature review of LCSCM will provide evidence of previous studies method of CF in the supply chain.

As this chapter deals with literature review, the chapter will adopt and adapt content analysis method employed by Seuring (2013) and Stechemesser and Guenther (2012) with some modifications. The chapter has no classical structure but will be structured as follows: the method of content analysis with some descriptive information of previous studies, findings of the content analysis, discussion of the findings and conclusions.

METHODOLOGY

This chapter has followed a systematic review approach to build knowledge of the topic (Seuring, 2013; Stechemesser & Guenther, 2012). There are several steps taken to begin literature review analysis. The steps are as follows:

Step 1: *Selecting research questions, databases and appropriate search terms.* In this step, developing a research question to begin searching for journal articles is important. In this chapter, the research questions are “what is LCSCM?” and “what is the measurement of LCSCM?” Then, the databases used are: Elsevier (www.elsevier.com) and Emerald (www.emerald.com). Next is the search terms used to find articles from those databases. Even though this chapter is focusing on LCSCM, other related supply chain keywords should not be neglected because based on early readings, these keywords are used widely to explain LCSCM. Thus, the relevant search terms are:

- Carbon footprint supply chain management
- Low carbon supply chain management
- Environmental management supply chain
- Renewable energy supply chain management
- Green supply chain management

Step 2: *Applying practical screening criteria (Filter 1).* This step requires filter management from those databases. Filters are used to select only relevant publications. In this chapter, the criteria includes latest five years publications to ensure the relevancy of the topic and findings and only journal articles will be taken into consideration. In addition, only business management or supply chain and operations clusters journals are taken. Some of the examples include:

- Journal of Cleaner Production
- International Journal of Production Economics
- Industrial Marketing Management
- Renewable and Sustainable Energy Reviews
- Resources, Conservation and Recycling
- Ecological Economics
- Energy Policy
- Journal of Environmental Management
- European Journal of Operational Research
- Journal of Operations Management
- Industrial Marketing Management

Step 3: *Sorting and generating theme for the study (Filter 2).* After the completion of step one and two, as many as 910 journal articles were recorded. These articles are then managed by reference management software to help with sorting and generating theme of the study. Theme generation is to identify all keywords used by scholars in regards to LCSCM. The

management software used for this chapter is Qiqqa (www.qiqqa.com). Other than managing references, Qiqqa also is used to import missing metadata. For example, the title, year, author, journal publication, issue and page number of the article need to be checked and corrected. This software also used to remove any duplicate articles due to bulk downloads from several databases. The advantages of using Qiqqa is that it can provide another layer of filter to the current filtered articles. This will enable user to extract specific information and select most appropriate articles. Below is the step taken using Qiqqa to apply Filter 2 for 910 journal articles:

- Adding all 910 journal articles into Qiqqa software
- Using BibTeX Sniffer, a function in Qiqqa to identify missing metadata and information so that keywords of every journal articles can be identified correctly and used for the next step
- Qiqqa software will generate tags and autotags based on all journal articles
- Presenting Filter 2 results (see Table 1)
- Re-apply filters for measurement of LCSCM. Due to the first objective of this chapter is to investigate LCSCM as an outcome, this step of re-apply filters for measurement is to specifically answer second objective of this chapter.

Step 4: *Extracting relevant information.* In the final step, reference management software will be used to see pattern and identify quality articles for further investigation. Then, manual analysis of articles is required to extract information for the purpose of the study.

FINDINGS

This section is structured according to review protocol such as information on author, year, publication and focus of the paper. Out of 910 journal articles (after Filter 1) that have been downloaded, only 246 journal articles (after Filter 2) are identified as important in Qiqqa that meet all search criteria.

In this chapter, for the purpose of review protocol (descriptive information), all 910 journal articles will be used while for author, country and focus will used 246 journal articles as basis. This is because 246 is more specific and smaller number that can give narrow or focus answer while the bigger number (910) will be used to capture general information of LCSCM. The last part of protocol, which is measurement of LCSCM needed manual analysis of 246 journal articles.

By using filter function performing inclusion and exclusion of criteria, descriptive analysis based on Table 2 protocol is able to be collected. Noted

that these articles have been given filters in step two and step three as discussed in methodology section. This section will start with bibliographic analysis for LCSCM and then analysis specifically for measurement. This is because the objectives of this study is twofold: 1) outcome of LCSCM and 2) measurement of LCSCM.

Table 2. Example Review protocol

Bibliographic Data	
Tag and Autotag	What is the highest keyword used in the publication?
Author	Who has the highest publication?
Country	Which highest country is subject of the publication?
Year	What year is the highest publication?
Publication	Which database has highest publication?
Focus of measurement	What is the main measurement of LCSCM?

Bibliographic Analysis

Qiqqa software has helped to identify keywords frequently used in the journal articles. Tags are given by author or journal publication based on keywords or key terms proposed by author or publisher. Based on 910 journal articles, renewable energy has the highest number (75) followed by supply chain management (73), LCSCM (69), GSCM (17). These are direct keywords that can be found in the journal articles and it shows that indeed low carbon studies are increasing in popularity in the literature. Renewable energy study which is a practice contributing towards LCSCM is an important study for future research to be undertaken by scholar. On the other hand, the Autotag of Qiqqa, after learning the pattern amongst 910 journal articles identify environmental management (497) and low carbon (257) as highest used keywords throughout all journal articles.

LCSCM studies has garner many interest from scholars both engineering and management approach. It is thought that engineering focus scholars will top the list since these scholars published more in LCSCM literature. However, interestingly management focus scholars has published journal articles on LCSCM more than engineering focus scholars. Top scholars are Joseph Sarkis (17), Kannan Govindan (17), Angappa Gunasekaran (13), Qinghua Zhu (11), Stefan Seuring (9) and Chunguang Bai (8).

The other interesting fact is the country where the studies being conducted. The findings are China (32), India (11), Malaysia (9), UAE (6), Australia (4), Brazil (4), Iran (3), Turkey (3), South Korea (2) and the UK (2). It is surprising to see Asian countries topping the list due to availability of data and LCSCM awareness are stronger in developed countries especially in Europe and USA. However, this information should not be taken literally because nowadays many scholars are able to conduct research almost everywhere in the world and collaborate with many scholars around the world. Also, some of the journal articles do not mentioned any country of study

due to type of article is either conceptual or using data generation software. Nevertheless, those top countries are giving good signal showing those countries are increasing knowledge of LCSCM.

The journal articles by year is also important because it can show a pattern of latest trend or future research direction. Out of 910 journal articles on LCSCM, the year 2014 had seen many journal articles been published in terms of LCSCM (227) while in the year 2015, there are 165 journal articles. On the other hand, the year 2012 and 2013 has 153 and 148 journal articles on LCSCM respectively. Looking at year 2016, even though it is not even half a year there are already 21 journal articles on LCSCM. This shows the strength of LCSCM studies in recent years.

The other part of analysis aim at the highest publication databases between Elsevier and Emerald. According to the analysis, Elsevier has the highest number of journal articles on LCSCM with 663 journal articles and Emerald database have 247. However, the number of management focus articles mostly are available in Emerald database but many top scholars have their publication in Elsevier database because it holds several reputable journal publications.

Next, the focus of study captured from specific 246 journal articles are renewable energy, manufacturing, climate change, GSCM, supplier, risk management, carbon emissions and LCSCM, performance and environmental management. These keywords are important for scholars. It is because all of these articles embedded these concepts and published in reputable journal publications. Thus, for scholars to publish in good journal publications, scholars should incorporated these keywords in their study.

Lastly, the second objective of this chapter is measurement of LCSCM. Surprisingly, there are only 442 journal articles on measurement keyword and out of that number, only 22 journal articles are on LCSCM measurement or LCSCM performance measurement. This findings confirm the gap in the literature. By manually navigates through these articles, the measurement of LC-

SCM is indeed depending on the underlining theory and type of measurement. Most journal articles on performance measurement are using Game Theory to measure LCSCM while the most influential management theory used for LCSCM measurement are Institutional Theory and Complexity Theory. The type of measurement used in LCSCM literature are mathematical or formula based studies with auto generated dataset and the most common method used is qualitative case study. This finding however is also raised by Lee (2011) who suggested more qualitative research should be undertaken to gather empirical results. This study on the other hand is looking at the measurement perspective. Since there are plenty measurement studies using qualitative methods, this chapter has identified qualitative method as top measurement of LCSCM.

DISCUSSION, FUTURE RESEARCH, AND RECOMMENDATIONS

Based on findings of this content analysis, the direction of LCSCM is clear. The first direction is that since renewable energy, SCM and GSCM are practices of LCSCM and among most used keywords, it define LCSCM as an outcome of the study. Scholars are shifting their attention from GSCM because it is heavily research and this has confirm LCSCM as the focus of the study or dependent variable. The second direction is scholars should embedded renewable energy and LCSCM in their study because it is the future trends in the literature.

There are two groups of scholars for LCSCM namely engineering focus and management focus. Even though engineering focus articles are plenty in the literature but management focus has established as more significant. This is due to several management focus scholars such as Sarkis, Govindan, Gunasekaran, Zhu and Seuring are publishing in reputable journal publications. In addition, in the business management and sup-

ply chain and operations clusters, management focus or approach is more appropriate because firms decision maker are top management that has little understanding of technical terms. While engineering focus scholars are also publishing journal articles with practical implications, it is more on process or technical approach. Thus, it is recommended for future research scholars to adopt management theory in their studies to ensure contribution to practitioner and policymakers are strong and to be able to publish in reputable journal publications.

This chapter only look into Elsevier and Emerald databases, which suggests that future research to include other databases. On the other hand, looking at the focus of the study out of 246 journal articles, LCSCM, risk management and manufacturing are all related to one another. These keywords suggest that LCSCM should be studied in the context of manufacturing industry and LCSCM is part of risk management strategy for firms. Perhaps, practitioners should consider LCSCM in implementation of risk management at firm.

In terms of contribution of this chapter to practitioner, by understanding the challenge in gathering real data for CF, firms should support the climate change mitigation strategy through public disclosure of carbon emissions data. In addition, practitioner should take note that the trend of renewable energy has already begun replacing fossil energy for power generation. On top of that, LCSCM has been an outcome that firms pursuing. Thus, practitioner need to start practicing LCSCM and GSCM to stay competitive.

An alarming finding is that there are only 22 journal articles on LCSCM measurement. This is in line with research gaps where scholars are finding it difficult to collect data of carbon emissions (Henri & Journeault, 2010; Lee, 2012; Matthews et al., 2008; Nakajima et al., 2014). As for the question “what is the measurement of LCSCM?” with current literature used in this chapter, management approach is more fruitful

and the use of qualitative study is more favorable because mathematical analysis mostly has not been tested with real data yet. The future research should then look at “how to measure LCSCM?” using qualitative study.

CONCLUSION

In summary, it can be confirmed that LCSCM is an outcome of study and the measurement of LCSCM depends on the type of study (theory used and method used in the study). Therefore, more study on LCSCM measurement is needed to generalize and standardize the content analysis. Finally, this chapter would like to highlight the importance of the findings especially the focus key terms such as renewable energy, LCSCM, GSCM and risk management. These are the main theme in the literature of LCSCM. In addition, the impact of limited literature on LCSCM measurement will definitely slow the adoption of LCSCM among practitioners and scholars.

KEY TERMS AND DEFINITIONS

Carbon Footprint: Carbon footprint is a term used to record carbon emissions by individual or a firm in order to see the impact of Greenhouse Gasses (GHGs).

Content Analysis: A robust and structured analysis of the literature.

Green Supply Chain Management: Managing and monitoring supply chain activities in accordance with environmental management practices.

Low Carbon Supply Chain Management Measurement: Method used to analyze the carbon emissions after it has been recorded.

Low Carbon Supply Chain Management: Elimination or reduction of waste along the processes in firms and members of supply chain while monitoring and reducing carbon emissions throughout the supply chain.

Missing Part of Halal Supply Chain Management

Ratih Hendayani

Telkom University, Indonesia

Yudi Fernando

Universiti Malaysia Pahang, Malaysia

INTRODUCTION

The awareness about halal products in the world, especially about halal foods, is increasing. Not only 1.57 billion Muslims in the world spreading over 57 Islamic countries (Halal Trade Globally, 2015), but many non-Muslims also regard halal products, halal foods especially, as a trend of a healthy lifestyle. This is an opportunity for certified halal foods manufacturers to make their halal products as a competitive advantage, of which the other food companies do not possess. Regarding the production processes, the label “halal foods” must not be a mere proclamation made by the manufacturers. Halal food producers must start managing their supply chain, particularly to decide and inspect on where they obtain the raw halal material and to ensure the optimal cleanliness and hygiene in the distribution, to ascertain that the raw materials or processed foods are free of contamination which may cause the products to become not halal. In fact, according to Zulfakar et al. (2014), with the complexity of the food trade in the world, especially in terms of distributing halal products throughout the world, consumers of halal food products are still not sure whether the products produced are completely in accordance with the principles of halal or the Sharia laws, whether or not the food is contaminated when distributed to the whole world.

To avoid problems of distribution with a long peak time, according to Omar and Jafar (2011), the company needs to ensure all supply chain net-

works comply with halal procedures in the entire supply chain globally. Currently, the market for halal products is widely distributed throughout the world. This leads to increased demand for halal products, not only from the Islamic countries but also from the non-Muslims. Hence the demand for halal products not only from Muslims but also from the others, causes halal products to become globally renowned. This phenomenon stresses the need for the halal supply chain. Supply chain on halal products, especially halal foods, means that every process and partner in the supply chain should be able to maintain the halal status of food products so that they can be guaranteed to be absolutely halal by the laws.

Given the importance of managing supply chains in halal products, many studies have discussed halal supply chain managements, such as in Tieman (2011), Tieman (2015), Alqudsi (2014), Zulfakar et al. (2014), Zulfakar (2011), Zailani et al. (2010), Ngah et al. (2014), Tieman et al. (2012); Aziz and Sulaiman (2014), Talib et al. (2013); Muhammad et al. (2009); Zailani et al. (2015), and there are still some other studies which are more focused on supply chain managements for halal foods. In addition, not all of these studies discuss halal supply chain management as a whole thus they are unable to capture the complexity of halal supply chain itself. Some just take the perspective of the consumer or distribution or simply in terms of the logistics of its course. The studies that discuss halal supply chain managements still have shortcomings in

translating the overall supply chain management and supply chain management to separate its role in logistics management. In gaining integrated halal products, logistics management is part of the supply chain management. Companies should be able to implement the concept of halal in the whole value chain system such as in procurement phase, processing, packaging, labeling, transporting, finance and logistics of food with the complete process. Unfortunately, the concept of halal logistics lacks focus and it is not enhanced by other following researchers who discuss halal supply chain managements so that there is still a lost concept on halal supply chain management (Kamaruddin et al., 2012). The lost concept is discussed in other studies, namely finance.

This chapter aims to explore the missing part of halal supply chain management, which previously was not defined as part of halal supply chain. Ensuring products' halal status, from the material sources until the products are bought by the consumers, has to be maintained with proper management, especially in the global food company. Halal supply chain is required to meet the demand from halal industry, and at the same time it should be aligned with the requirements of Sharia laws.

BACKGROUND

Every Muslim is required to consume halal products by its religion. Consequently, the growing Muslim population in the world means that the need for halal products continues to increase. The inter-religious tolerance and social relationships which are created between Muslims and non-Muslims allow the latter to start recognizing and realizing the benefits of halal products. These non-Muslims grasp the great benefits of halal products, in terms of hygiene, health, and quality. Consequently, the request for halal products arises, not only from Muslim consumers but also from non-Muslim consumers worldwide. In fact, according to Alqudsi (2014), the level of awareness

on the consumption of halal products and halal law of consumers around the world is increasing even from major non-Muslims populated countries, such as Australia. They are willing to pay more for halal products. Awareness of halal products needs to be accompanied with the knowledge of the meaning of halal and of the procedure about how the halal status of a product is maintained so that consumers are confident when consuming it. According to Rezai et al. (2012), we cannot simply guarantee that our products are halal only by avoiding its contacting with the haram material when the consumers buy our products. We have to go from the starting point to ensure that the product is not contaminated by haram materials or breaking any of the halal rules, from raw materials suppliers of products included in the manufacturing process to the distribution.

According to Tarmizi et al. (2014), one of the ways to avoid contamination in the process of transportation and distribution is the halal logistics, which involves logistics as a part of a supply chain involving in businesses, such as suppliers, manufacturers, distributors, and retailers, who will work together to meet needs for raw materials and distribute them to consumers. In addition to keeping out of contamination, halal logistics also plays a role to ensure that proper information on halal products is well received by consumers. It means that in order to obtain halal status, accordance of any detail logistic processes with Sharia principles is required, such as the procurement, distribution, raw materials, up through the supply chain, all must in conformity with the Sharia laws.

Tarmizi et al. (2014), Tieman (2013), and Kamaruddin et al. (2012), explain that halal logistics is a part of the supply chain, mainly a part of supply chain management of halal product which has a process that is in accordance with the general principles of Islam or the Sharia. The focus of this chapter is halal supply chain due to the larger scope of halal logistics and management that could have a direct impact on halal product itself that is distributed with the involvement of the supply chain actors, and also the process steps

in the supply chain companies. Moreover, based on Bahrudin, Ilyas and Village (2011) in Zulfakar et al. (2014), mention that the problems that can arise when the raw material of halal products obtained globally is that not all of the countries supplying raw materials is a Muslim country or under the supervision of Sharia law and Muslim rule, so that the raw materials which are derived from non-Muslim countries would be questionable in terms of its halal status. On the other hand, the demand for halal products from around the world is constantly increasing. So, in order to overcome doubts about the halal status of the products—the ones which gather its raw materials from non-Muslim countries—a comprehensive approach to halal supply chain management is required. It shall be well-managed and able to be applied globally in order to comply with the Sharia law, which is important for Muslim consumers. The goal of the halal supply chain management is to ensure that customers' satisfaction is achieved and that the halal status of food products remains intact throughout the entire supply chain processes. Zulfakar et al. (2014) also conclude that the integrity of halal food products must be protected by all means and all necessary steps should be taken by all parties involved in the supply chain to avoid cross-contamination that would cause the product to become non-halal or haram. So it takes an integrated management that can be applied appropriately and in accordance with the provisions of the Sharia, that is halal supply chain management.

Since halal supply chain management is very important for halal products industry, the application of halal supply chain management should be supported by the development of theory and study on halal supply chain management topic. However, literature in the field of supply chain management of halal foods is still limited. The review in Zulfakar et al. (2011) on halal supply chain only includes 41 sources related to the halal industry, starting from the procedure of halal manual to Malaysian halal standard, articles from newspapers, magazines, journals, brochures, slide presentations,

and halal-related relevant authoritative websites in Malaysia. The main limitation of the review is that they only focused on identifying processes, information flows, and the actors involved in the process of halal certification. Unfortunately, the discussion of halal supply chain management that is focused on the identification of supply chain process for halal products leaves a process that should be present in the process and can be found in the meaning and scope of a supply chain.

The meaning and scope of a supply chain can be observed from some definitions of supply chain management. According to Heizer and Render (2014), supply chain management is the management of raw materials into goods in process or semi-finished goods and finished goods that send the product to consumers through the distribution system. These activities include the traditional purchasing function, plus other important related activities. Meanwhile, according to Chopra (2013), supply chain management is the management of the flow of information, products, funds, between and fellow stage supply chain to improve the supply chain advantage. Council of Supply Chain Management Professionals (CSCMP) (2016) also states that supply chain management is the planning and management of all activities involved in procuring and activities of logistics that involve coordination and cooperation with the actors involved in the supply chain and integrate the management of supply and demand between companies that have the scope to support the coordination between the processes and activities in marketing, sales, product design, financial, and information technology. An overview of the halal supply chain management means that every definition and scope of supply chain management is in accordance with the principles of halal.

However, when viewed from the previous literature regarding halal supply chain management, such as Syazwan et al (2015), which already reviews some concept of halal supply chain management of other researchers such as Tieman (2013), elaborates the definition of halal supply chain as a management process of purchasing, distribution

and material handling, raw materials, which are then stored on a good supply of food or not, and the flow of information and administration of an organization involving the supply chain that can adapt to the general principles of Sharia. However, defining principles about halal supply chain in Syazwan et al. (2015) are still unclear because each researcher has a different interpretation.

These unclear halal supply chain principles are a result of there being a missing part of halal supply chain management definition from previous researchers. So, this chapter will discuss an advance definition and scope of halal supply chain through elaborations on the meaning of supply chain with the principle of Sharia as a whole, not just by definition alone, but its scope as well.

ISLAMIC FINANCING SYSTEM TO SUPPORT OPERATIONS OF HALAL SUPPLY CHAIN

Halal products have become the emerging issue of the world as predicted to be the next global market, as evidenced by the increasing demand for halal products and public awareness in the world about the benefits of halal products that are not only limited to a religious understanding or belief of one religion alone. Halal products are known to the world community as products that have the image of clean, healthy, and appropriate according to Sharia quality assurance procedures. The focus then is to guarantee quality, that it is clean, healthy and certainly must meet the criteria of the Sharia, that it is still maintained carefully when the procurement, distribution, and processing is done globally, which allows all of the processes carried out in different countries. Moreover, we have to focus on how products' halal status can be guaranteed or how to monitor the products so that they remain guaranteed halal even when the activities of logistics and supply chain actors may come from states which are not Muslim countries, or worse, from the places which even do not know the word "halal." In fact, some countries

which supply the raw material of halal products are countries known for its Muslim population as the minority, such as Thailand and American countries which supply a lot of raw materials for halal products in Indonesia, the largest Muslim country in the world.

To overcome this, companies can apply a particular supply chain management which is in accordance with the provisions of Islamic laws or the Sharia laws, as the solution of how the availability of halal products can be maintained and how they can be distributed throughout the world—with supervision from the source to the consumer is fixed in accordance with Sharia principles—that is called the halal supply chain management. The need of halal supply chain knowledge becomes one of the critical things that halal product industry should have to run their supply chain operation system, because without the knowledge, halal product industry does not have the guidelines on whether or not the companies' supply chain is already in conformity with the Sharia or Islamic law. So that, several studies on halal supply chain management are already conducted by some researcher with different scopes and focuses, such as Tieman (2011) that plans the basic requirements of halal food supply chain through in-depth interviews with qualitative, exploratory study. The study employs a frame of which the dependent variable is direct contact with haram, risk perception, and the independent variables are haram products, product characteristics (dry vs. wet product, bulk vs. together product), market characteristics (schools that had a different idea and local fatwa). The weakness of this study is that to measure the perceptions of customers, concrete tools for designing effective halal chain supply is needed, not only the perceptions of customers. Zailani et al. (2010), reveals that the industry needs to be provided with the appropriate training or motivational programs on issues of halal standard. The members of the industry, therefore, can be more innovative in improving their operations and more competitive in the world food trade. However, this model requires a com-

L

prehensive assessment of the suitability of existing supply chain. Also, Zulfakar et al. (2014) explain about several factors in improving the integrity of the food supply chain and provide a conceptual framework about this particular problem by using a conceptual paper through relational analysis. This study comes up with the idea that the factors in the supply chain of halal foods, such as certified halal, halal standard, traceability, halal, halal dedicated assets, trust and commitment among members of the supply chain, should be given serious attention to ensure the needs and welfare of consumers, that the halal foods can be satisfying for them and are well protected. Syazwan et al. (2015) have made a comprehensive literature review and its result is the critical success factors, which are: government support, transportation planning, information technology, HRM, collaborative relationship, halal certification, and halal traceability.

Based on a short overview of several previous researches above that discuss halal supply chain management, it can be seen that most of them focus on technical aspects during processes of halal supply chain and management, such as Sharia-based procurement, halal distribution, halal inventory, halal handling, halal product from raw to finished, halal information, halal documentation, halal logistics, halal value adding, halal supply chain members. They do not include other important parts of supply chain management. If we look again to supply chain management concept, it is defined as:

a set of integrated activities to manage upstream and downstream relationships with suppliers, manufacturers, distributors, retailers, and customers in order to deliver superior customer value at less cost, efficient and effective distribution, purchasing and procurement and other supply chain activities with a continuous flow of information and to deliver customer service and gaining competitiveness. (Verma and Seth, 2011)

Moreover, Chopra and Meindl (2013) define supply chain management as the management of

flows between and among supply chain stages to maximize total supply chain profitability, of which the supply chain flows are information, product, and funds. Thus, based on supply chain management definition, it evolves not only information and product but also a fund that has not been disclosed in the previous study of halal supply chain management.

Although the concept of Halal logistics on Kamaruddin et al. (2012) also includes companies financing system, most of other studies that specifically discussed Halal supply chain, finance is not included in Halal supply chain definition. Although in the definition and scope of the supply chain of Chopra or CSCMP, finance is mentioned. Wuttke et al. (2013) whose study focused on financial supply chain, because he thinks companies' managements often focus solely on the flow of products and information only, but less attention to cash flows involved in the process of such management. Wuttke et al. (2013) opinions are based on an understanding of supply chain management of Mentzer et al. (2001), which states that supply chain management focus on the coordination and cooperation of several stakeholders in the company to improve the flow of products, information, and finance throughout the supply chain. Given the importance of the involvement of finance in the management of the supply chain, in order to obtain an integrated supply chain Halal and fully covers all the important elements in Halal Supply chain principles.

Halal financial flow means that Islamic finance refers to the financial system of banking in accordance with Islamic law or sharia. According to Catherine (2015),

...the underlying principles governing Islamic finance mutually-risk and profit sharing between parties, guarantees of justice based on standards of Shariah compliance checks underlying Sharia-based business activities and assets. This encourages entrepreneurship, trade and commerce, but prohibit activities that involve Riba (interest), Maisir (gambling), and Gharar (speculative trad-

ing). There is a consensus among all Islamic law prohibits business operations involving interest and gambling, and they are in the production, distribution, promotion and sale of goods or services of non-Halal as alcohol and pork, and entertainment facilities immoral such as brothels, pubs, massage parlors and discotheques.

The role of Halal financial principles in Halal supply chain will be one of the important things in Halal product industry, beside integrated operation and coordination through supply chain management that comply with Islamic law. Halal product industry also can completed the Halal brand of Halal products with Halal investment, Halal cost, and Halal fund. Halal financial gives assurance to customers. Furthermore, Surah Al-Baqarah: 275 in Holy Quran states that "...but Allah has permitted trade and has forbidden interest (*Riba*)..." It states that in Islam, if a transaction using *riba* then it is forbidden or not Halal (Haram). If the transaction is Haram, automatically the product Halalness also becomes questionable, as stated in hadist Ibn Masood (Radiyallaahu Anhu) that narrates Rasulullah Sallallaahu Alaihi Wa Sallam, "...who acquires haram wealth and gives charity from it, and it is not accepted from him. If he spends from it, he does not have any blessing (*barakah*) in it..." (Musnad Ahmad, Sharh As-sunnah; Mishkaatul Masaabih pg. 242, Qadeemi). Besides to fulfil the Islamic law requirement for Halal product, it also can completed the Halal supply chain definition as one package because if the financial system inside Halal supply chain does not comply with Islamic law, it is not *barakah* and doubttable. Islamic financial system is very important to support and improve operations of Halal supply chain.

SOLUTIONS AND RECOMMENDATIONS

Based on the study, as well as the exposure of the background and the main focus, the problem

is the loss of an important part of supply chain management that is not discussed in previous research of Halal supply chain management studies which is very important for Halal supply chain operation. The concept of Halal that has not been addressed in previous studies are finance or acquisition of funds and cash flow, which all must comply with Sharia or Sharia finance. Based on the discussions in main focus, Islamic financial is the important things to make sure all investment, cash flow, and fund complies with Islamic law. Because of the very important role of Islamic financial that can influence the Halalness of the product, Islamic Financial should be applied and included in Halal supply chain. If the finance is not Halal then the supply chain operation cannot called a Halal supply chain. So that, to complete the "Halal" in Halal supply chain and advance it operations, then it is recommended to include Islamic financial system in Halal supply chain. When the entire stream in supply chain, such as the flow of products through Halal logistic, the flow of information through the involvement of all players in the supply chains, and the flow of finance related to cash flow, and every operation involved in the supply chain management can be applied to the Halal supply chain management, then it will create an integrated system that is perfect for Halal products industry. The new meaning of Halal supply chain management that already involving Islamic financing can be defined as:

...planning and supply chain management ranging from Sharia procurement, distribution Sharia, processing of Halal products through the logistics Halal, Halal certification process, maintenance of Halal products and Halal certification by monitoring the flow of Halal products, information-based Islamic and Halal finance involves cooperation among supply chain actors who have good cooperation with the principles of Islamic cooperation.

This new definition can be a guidelines for new perspective about Halal supply chain management.

FUTURE RESEARCH DIRECTIONS

This chapter highlights Islamic financing that should be included in Halal supply chain and bring new definition that more completed and more integrated for Halal product operation requirement. But this concept still need to be assessed by the quantitative study and to be tested by various Halal product in Muslim and also non-Muslim country. Not all Muslims and, especially, non-Muslims are aware about Islamic financing system as well as Halal food. Future study can research about Muslims and non-Muslims perception about Islamic financing in Halal supply chain. Not only the consumer, but supply chain partner and the authority also should be aware about Islamic financing system when operating the Halal supply chain.

CONCLUSION

As pressure from consumers' demands of Halal products, supply chain should focus on Halal industry. Given the importance of Halal supply chain management, it needs to be studied and developed. And this chapter increase of the significance definition of Halal supply chain management by adding a financial component that does not exist in the previous study, so the idea of Halal supply chain definition in this chapter is:

the planning and management of the supply chain from the Sharia procurement, Sharia distribution, processing Halal products through Halal logistics, Halal certification process, Halal product maintenance and Halal certification by monitoring the flow of Halal products, Sharia-based information, and Halal financing involve cooperation among supply chain actors who have good cooperation with the principles of Islamic cooperation.

KEY TERMS AND DEFINITIONS

Halal Supply Chain: Planning and supply chain management ranging from Sharia procurement, distribution Sharia, processing of Halal products through the logistics Halal, Halal certification process, maintenance of Halal products, and Halal certification by monitoring the flow of Halal products, information-based Islamic, and Halal finance involves cooperation among supply chain actors who have good cooperation with the principles of Islamic cooperation.

Halal: Every things that allowed by the Islam laws.

Islamic Financing: According to Catherine (2015) the underlying principles governing Islamic finance mutually-risk and profit sharing between parties, guarantees of justice based on standards of Sharia compliance checks underlying Sharia-based business activities and assets. This encourages entrepreneurship, trade and commerce, but prohibit activities that involve “Riba” (interest), “Maisir” (gambling) and “Gharar” (speculative trading). There is a consensus among all Islamic law prohibits business operations involving interest and gambling, and they are in the production, distribution, promotion and sale of goods or services of non-Halal as alcohol and pork, and entertainment facilities immoral such as brothels, pubs, massage parlors and discotheques.

Supply Chain Flow: (2013) The flow of information, products, funds, between supply chains to improve the supply chain advantages.

Supply Chain Management: (2011) A set of integrated activities to manage upstream and downstream relationships with suppliers, manufacturers, distributors, retailers and customers in order to deliver superior customer value at lesser cost, efficient, and effective distribution, purchasing and procurement, and other supply chain activities with a continuous flow of information and to deliver customer service and gaining competitiveness. Verma and Seth.

Notions of Maritime Green Supply Chain Management

Fairuz Jasmi

Universiti Sains Malaysia, Malaysia

Yudi Fernando

Universiti Malaysia Pahang, Malaysia

INTRODUCTION

Intercontinental trade relies heavily on maritime transportations to carry various cargoes for catalyzing global import-export trade. Roughly about 80% of international trade by volume and over 70% by value is carried by maritime operations globally (Cheng, Farahani, Lai, & Sarkis, 2015). As a vital component of life-line trade for various manufacturing companies all over the world, maritime supply chain have established new opportunities and unforeseeable challenges. The challenges faced by maritime supply chain dampened in the increased rate of climate change and global warming during the precedent decade (Lai, Lun, Wong, & Cheng, 2011). In this respect, carbon dioxide (CO²) and other greenhouse gases (GHGs) are emitted through the burning of fossil fuels from maritime transportation are responsible for a host of global environmental concerns. Playing the critical role as a major transportation and intermediary to assist trade flows in the global supply chain (Wong, Lai, & Cheng, 2009; Yang, Marlow, & Lu, 2009), many issues have been raised in operational context of maritime supply chain especially on environmental issues. As such, environmental protection has been extensively discussed by stakeholders, businesses, authorities as well as political leaders globally (e.g., Boykoff & Yulsman, 2013; Boykoff, 2009; Revkin, 2009; Rosenthal, 2009). In scholarly field, there has also been a surge in researches committed to address the related issues of environmental issues (e.g., Lee

& Kim, 2011; Ostrom, 2008; Wong, Lai, Shang, Lu, & Leung, 2012). The tightened environmental regulations imposed by International Maritime Organization (IMO) to the maritime sectors also contribute to this rising green trend (Sulaiman, Akmar, & Michel, 2013). As a result of this 'green' pressure, numerous maritime organizations have gradually begun to react to environmental concerns by embracing green supply chain management (GSCM) and other sustainability concept in their supply chain operations (Lai et al., 2011).

To the author's limited knowledge, relatively a small amount of studies have discussed GSCM dimension in the context of the maritime supply chain as well as sustainable notion of maritime green supply chain management (MGSCM). Preceding studies have stressed on tangible aspect of maritime operation such as sewage pollution, air pollution, and greenhouse gas (GHG) emissions (Cariou, 2011; Corbett, Wang, & Winebrake, 2009; Giziakis & Christodoulou, 2012; Hoffmann, Eide, & Endresen, 2012; Lirn, Lin, & Shang, 2014) but no intangible aspect in term of organizational management perspective of internal or external organizational capabilities can be found. If there is, it is literally a new domain in maritime supply chain and it is sensible to fill the gap in the literature by examining the GSCM dimensions that can be conceptualize towards defining the notion of MGSCM. Accordingly, the purpose of this paper is not to investigate empirically the dimension of MGSCM but to identify key GSM capability factors and examine the accountability of the

GSCM concept to be aligned with MGSCM's notion of sustainability in the context of maritime supply chain. Thus, in the subsequent chapters, we would discuss on preceding literature with regard of GSCM definition and theory as well as MGSCM notion conceptualized from GSCM to support this paper.

BACKGROUND

GSCM as a Novel Concept of Sustainability

The issue of sustainability in the context of supply chain management (SCM) has been discussed using various terms in the prior literatures. A number of modern literature reviews on GSCM and sustainability have been published in this respect e.g., (Abbasi & Nilsson, 2012; Carter & Rogers, 2008; Gimenez, Sierra, & Rodon, 2012; Sarkis, Zhu, & Lai, 2011; Seuring & Muller, 2008). Early sustainability practices and concepts tended to stress on environmental impacts but, gradually many latest studies adopted the triple bottom line impact that includes environment, economic, and social dimension. Although similar to the concept of SCM, the boundary of GSCM concept is dependent on the supply chain concurrently with the product; however, adding the "green" and "sustainable" component to SCM involves further aspect of addressing the influence and conceptual relationships between SCM and the environment. Consequently, GSCM distinguish the disproportionate of supply chain processes towards environmental impact in an organization. GSCM practices in this sense, are acting as an environmental and operational structure of improvement to catalyze an operational planning that numerous of organizations nowadays are promoted to tackle (Rao & Holt, 2000). Accordingly, a diverse of definitions of GSCM present in the literature. The subsequent paragraph sum ups some of the definitions of GSCM that have emerged in

the recent literature that can be linked towards this paper's conceptualization of MGSCM concept. For examples GSCM can be interpreted as:

1. Network management of sustainable supply chain (Cruz & Matsypura, 2009);
2. Corporate social responsibility network in sustainable supply and demand (Cruz & Matsypura, 2009; Kovacs, 2004);
3. Environmental management of supply chain (Sharfman, Shaft, & Anex, 2009);
4. Green procurement and green purchasing (Günther & Scheibe, 2006; Min & Galle, 1997);
5. Environmental purchasing (Zsidisin & Siferd, 2001);
6. Green and environmental logistics (Murphy & Poist, 2000); and
7. Sustainability in supply chains (Bai & Sarkis, 2013; Linton, Klassen, & Jayaraman, 2007).

Based on GSCM definition mentioned, GSCM is a resolute effort throughout the organization and is more than plainly putting some green dimensions in place, but rather a consistent and holistic enhancement and improvement of the environmental dimension in all levels of internal and external organizational management perspectives (Davies and Hochman, 2007). GSCM in general can also be used practically in any industrial and business context within the management structural framework. The research on sustainability issues in supply chain has been conducted by numerous scholars in the past regarding the theory and practical contribution in various industrial backgrounds such as manufacturing field (Zhu & Sarkis, 2004), product innovation (Lee & Kim, 2011), organizational management (Alfred & Adam, 2009), automotive (Luthra, Kumar, Kumar, & Haleem, 2011; Olugu & Wong, 2011) and other fields. Therefore, GSCM can also falls within the purview of increasing literature on maritime perspective of supply chain and operational management outlooks.

MGSCM as a Concept of Sustainable Maritime Supply Chain

In the perspective of GSCM in maritime supply chain, various literatures emphasized sustainability within maritime operations in diverse terms. Psaraftis (2016) used the term green maritime logistics which defines as an effort to achieve adequate environmental performance in the maritime supply chain, while at the same time fulfilling traditional economic performance dimension. While Cheng, Zanjirani Farahani, Lai and Sarkis (2015) defined sustainable maritime supply chain as sustainable maritime SC which means the integration of maritime organizational units (ports, shipping companies, etc.) in a supply chain system and organization of materials (container, bulk and general cargoes), information, and monetary flows in order to accomplish customer needs while at the same time improving the economic competitiveness through conformity with regulations to control social and environmental impacts. The conceptual term “green shipping practice” (GSP) in defining sustainability has also becoming prominently used in the context of sustainable maritime supply chain to address this rising issue. As Lun et al. (2013) stated, GSP capability focuses mainly on enhancing efficiency in operational condition as well as reducing harmful impact of supply chain actions towards environment through internal and external GSCM capabilities. While others defined sustainability in maritime supply chain as business approaches and actions that meet the current and future needs of the maritime sector and its stakeholders while protecting and sustaining human and natural resources (AAPA, 2007). Additionally, Lai et al. (2011) proposed a theoretical framework with a few propositions to define sustainable maritime practices in the maritime context. They identified and defined six dimensions of sustainable maritime operations, which include organizational policy and procedure, maritime documentation, maritime equipment, shipper cooperation, maritime materials, and shipping design and compliance. Other researchers

have also used the term green management to link sustainability in maritime supply chain in prior literature. Zhu, Sarkis and Lai (2007) deposited that environmentally sustainable management, or the so-called ‘green management’, has also become known as an imperative management topic for organizations to attain profitable operation and market share while at the same time commit towards environmental protection. According Shrivastava (1995) organization’s improvement in competitive positions and performance could be increased by adopting green management practice (GMP) and concurrently decrease the harmful effects of their operations on the natural environment at the same time. Furthermore, sustainability in maritime supply chain in additional literature review encompasses the need to understand the basic conceptual ground of green supply chain management (GSCM) to be integrated in maritime industry. Finally, it is beyond this modest scope of paper to elaborate much on other researches on GSCM, but it is understandable at this point that incorporating environmental concerns into management approaches has become progressively significant for organization to achieve competitive advantage and lessen the environmental impact. Thus, in this paper, we concluded that the GSCM concept can be extended into the term maritime green supply chain management (MGSCM) that refers the integration of GSCM in maritime context; and define it as integrating environmental concerns into the inter-organizational practices of SCM in maritime context to ease the flow of operation in maritime supply chain system.

Conceptualizing MGSCM via GSCM Concept

In this section, we concluded that the dimensions of sustainability of MGSCM are needed to be drawn for successful completion of GSCM. Thus based of understanding from previous chapter, we defined MGSCM’s notion in this paper based on five dimensions of GSCM, that is, green information and communication system (GICS), green value added

logistic service (GVALS), green supply chain integration practice (GSIP), shipping design and compliance (SDC) and green financial flow (GFF) taken from GSCM literatures. We concluded that the conceptual notion of each MGSCM dimension can be presented and defined as:

1. **Green Information and Communication Systems (GICS):** Defined as the systematic application of sustainability in various processes of IT and communication management in order to reduce environmental impact (Kehoe & Boughton, 2001; Prajogo & Olhager, 2012; Swaminathan & Tayur, 2003). According to Preuss (2002), GSCM can only become a strategic organizational capability if it could simultaneously monitor manufacturing, purchasing and selling process collectively together. The benefit of implementing the information system integration technology in maritime supply chain helps the organizations to synchronize supply chain process and close collaboration with partners through the integration of data related information to the production schedules, managing item in inventory, demand forecasting, as well as managing the production quality (Li, Yang, Sun, & Sohal, 2009). It is also wise to approach the information flow of GICS in the perspective of just in time (JIT) context within the sector. According to Swafford, Ghosh and Murthy (2008) information technology supports the efficiency of information flow in term of integrated JIT schedules and set up the effective information links that help to reduce the shipment discrepancies time. The advantages of this system of GICS would provide the maritime industry with better management mechanism of storing, accessing, sharing as well as analyzing the information needed in real time and with high efficiency.
2. **Green Value Added Logistic Services (GVALS):** Defined as the systematic application of sustainability in various processes

value added logistic in supply chain to reduce ecological impact that encompasses diverse dimensions of emotional element, social and functional value (Sweeney & Soutar, 2001). From broader perspective, GVALS can be considered as a component of GSCM that intend at mixing together environmental philosophy into conventional SCM and logistics management through product design (in production phase), supplier assortment and selection as well as material sourcing, inbound and outbound shipping, manufacturing processes, waste reduction control, product wrapping and packaging, distribution to end customers, and reuse and end-of-life product returns for recycling (Beamon, 1999; Linton et al., 2007; Srivastava, 2007). GVALS practices like the employment of green and recycled packaging materials as well as green packaging designs and techniques, could largely diminish packaging waste and cost associated using conventional method (Hung Lau, 2011) if extended properly into maritime operations. From maritime logistic perspective, GVALS practices such as optimization and consolidation of orders, schedules as well as routes taken in shipping operation could reduce the delivery frequency and ultimately cut the fuel consumption (Rao, Grenoble, & Young, 1991). Finally, the organization could implement the GVALS by extending the scope towards the employment of fuel-efficient transportations as well as alternative energy sources to decrease environmental impact (Yusuf et al., 2013).

3. **Green Supply Chain Integration Practices (GSIP):** Defined as the systematic approach of integrating sustainability in various processes of supply chain in order to reduce impact to environment and gain efficiency to the extent of intra-organizationally or inter-organizationally processes to achieve significance value to the final customer demand with cost effectiveness (Frohlich

& Westbrook, 2001; Van Der Vaart & Van Donk, 2004). Handfield, Walton, Sroufe, & Melnyk (2002) suggested that throughout the value chain process, environmental sustainability efforts should be integrated accordingly to enhance the value creation with supply chain partners. As Vasileiou and Morris (2006) added that integration process in GSCM such as friendly processes, products, and services requires a combination and unification efforts by all component members of supply chain to avoid sub-optimization at the partner level.

4. **Shipping Design and Compliance (SDC):** Defined as the systematic approach of sustainability in various processes of shipping design as well as conformity with sustainable compliance in order to decrease impact to environment and gain efficiency (Chang, 2012). SDC emphasis a preventive focus on maritime technologies and design to mitigate the environmental harms caused in maritime operations (Lai, Wong, Lun, & Cheng, 2013). The dimensions of compliance in SDC involve energy saving measures, shipping equipment reuse, recycling, and recovery, targeting to mitigate ecological harm due to maritime activities. SDC is valuable for improving operational efficiency through waste elimination in the supply chain processes (Hart and Ahuja, 1996), increasing financial savings through reusing of shipping equipment and reducing redundant processes through efficient waste management. SDC in maritime context helps to manage and prevent emissions and effluents in compliance with environmental regulations for general performance gains.

5. **Green Financial Flow (GFF):** Defined as the systematic approach of sustainability in various processes of financial management and accounting in order to reduce impact to environment and improve sustainability in a long term (Cairns, 2000). It includes the commitment from management level,

the identification of monetary measurement to measure traditional private internal costs that directly affect the green bottom line of the balance sheet. In this sense, the cost would be the direct costs, such as raw materials and labours, which are attributed to a production items or department and indirect costs, or overheads, such as rent, administration, depreciation, fuel and power. Above all, externalities factor such as social, operational, economic and environmental costs that impact the external environment of organization operation must also be taken into account in green financial flow. For MGSCM capabilities, green financial flow consists of incorporating monetary savings from new cleaner technologies consequential in lower pollution and better health, new markets and using alternative of raw materials or operation processes in maritime supply chain system. Using a framework of green accounting, green financial flow in MGSCM would mean that investment decisions in managing supply chain are made by comparing the overall private and social costs against the private and social benefits. In this sense, via a lifecycle assessment, maritime companies can make decision based on environmental impacts calculation at each stage of supply chain system, from production, transshipment and final disposal of product or services to enhance green performance.

FUTURE RESEARCH DIRECTIONS

Although many studies (e.g., case studies and survey-based empirical methods) have been carried out in GSCM context, they have not completely dealt with each and every aspect of MGSCM. In this regards, there are some areas around MGSCM dimensions that still require further empirical study to conceptualize the notion of MGSCM in this paper. Therefore, future detailed empirical investigation is needed to be carried out

in maritime supply chain domain to truly define the sustainable notion of MGSCM based on the growing literature of GSCM dimensions. Future studies should be included other GSCM practices and dimensions in exploring accountability of the whole concept of GSCM empirically to support the sustainable notion of MGSCM. We are optimistic that the novel MGSCM dimensions can be adopted and materialized in the future. At such, for future studies, the conceptual notion of MGSCM dimensions can also be extended into performance related study that focusing on outcome measurement of economic, environmental, operational and social performance.

CONCLUSION

With regard to the rising global awareness of environmental protection, businesses have employed their GSCM to improve their core competitive advantage. MGSCM derived from GSCM capabilities is a progressively widely-diffused notion that is seeking to improve environmental performance in maritime supply chain context. MGSCM practices, which can be viewed as a cross-organizational and closed loop capability that reduces the ecological impact of maritime operation without sacrificing quality, cost, reliability, performance or energy utilization efficiency. We assumed that, by engaging in MGSCM-related knowledge and capability. Not only does reduction of pollutants and decrease of cost; it also gives the organization involved in improved sustainable competitiveness. Even though no empirical evidence presented in this paper, we are positive that MGSCM dimensions of GICS, GVALS, GSIP, SDC and GFF can be translated into sustainable notion of MGSCM based on general understanding of GSCM literatures. This is due to the fact that the key themes that came out of the MGSCM literature derived from GSCM over the last decades are more or less the same holistic concept of greening the product design, material management, manufacturing process, distribution

and marketing. By the assessing the MGSCM notion of organizational capabilities, this paper has establish new theoretical ground that contributed significance knowledge towards increasing body of literatures in green management.

KEY TERMS AND DEFINITIONS

Green Supply Chain Management (GSCM):

Is about assurance to all usual and traditional supply chain deliveries while integrating the social and environmental concern in every phase of supply chain system to ultimately diminish or lessen product's ecological footprint.

Maritime Green Supply Chain Management (MGSCM): Defined as integrating environmental concerns and practices into the inter-organizational practices of SCM in maritime context to ease the flow of operation in maritime supply chain system.

Maritime Supply Chain: Defined as the movement of cargoes and related support service involving two substantial locations using maritime and land transportations.

Supply Chain Management (SCM): Defined as managing flow of materials, information, and finances as they move in a process from supplier to manufacturer to wholesaler to retailer to consumer.

INTRODUCTION

Outsourcing as an Academic Disciple

Outsourcing as may be described as procuring goods or services needed by a business under contract with an external supplier. If one were to assess this definition in a literal sense then any form of trade could be viewed as outsourcing. We have narrowed our research to focus on information technology (IT) outsourcing. The relatively short history of IT seems to correlate with the defined term, which was only added to some standard dictionaries since 1979. This fact would indicate a brief period of existence before the inclusion. Previous research (Hamidi, Farahmand, Sajjadi, & Nygard, 2012; Kumar, Shankar, & Yadav, 2011; Mathirajan, Manoj, & Ramachandran, 2011; More & Babu, 2012) generally supports this historic trend, but a hard date indicating the birth of outsourcing probably does not truly exist. One of the earliest and most prominent example of IT outsourcing is with Electronic Data Systems (EDS) in 1962, which resulted in a very slow adaption.

The following chapter will look at outsourcing through several different lenses. Initially, some of the historical and current trends that exist in outsourcing IT, followed by some of the major services have been and are being utilized

by firms looking to outsource, outside tax incentives such as tax inversions. Next, an assessment of the benefits and risks of engaging in an IT outsourcing relationship will be discussed. In this section, some of the classical reasoning behind management decisions to outsource and the risks that managers should be aware of when entering into this relationship. Finally, this research effort returns to EDS and others to profile applications of IT outsourcing before moving on to look at the possibilities in the future of outsourcing.

The focus on process efficiency and cost control efforts has encouraged firms to look for creative means to structure their business efforts, especially in, customer service, IT, and lean operations (Beldona & Tsatsoulis, 2010; Bhamu, Khandelwal, & Sangwan, 2013). Outsourcing has become a common practice, especially in the area of information systems/technologies (IS/IT) among large and medium size enterprises (MSE) globally. For example, Spanish firms (up to 83.6%) outsource at least some IS function nationally (Gonzalez, Gasco, & Llopis, 2010). Although a growing trend, there has been limited research on how IT outsourcing has changed the traditional characteristics of this industry and the attitudes of existing IT professionals on the phenomenon over a period of time.

The aim of the present research is to specifically evaluate how IT outsourcing has affected

the following areas of research (i.e., the time required for IS managers to perform their jobs; the characteristics of the IS manager's working environment or post; the type of knowledge and skills required to carry out the IS manager's professional activities. A number of researchers (Pettersson & Segerstedt, 2011; Pradhananga, Hanaoka, & Sattayaprasert, 2011; Von Haartman, 2012) have investigated IT within an industrial focus, as compared to the service sector, which is differentiated as general services and IT-intensive (i.e., financial institutions, insurance companies, the tourism sector, attorneys, supply chain integration and collaboration, to name a few). The operations manager, on-the-other-hand, generally emphasizes the strategic consequences of job satisfaction and productivity as a function of industrial outsourcing.

This is because of rapid technological change, high investments firms have made in IT and the great interest in outsourcing have made these executives the target of many surveys. (Gonzalez, et al., 2010)

The results from this study suggest a weak association between IS outsourcing and job performance, work post, and required knowledge and skills (Willcocks, Hindle, Feeny, & Lacity, 2004). In relation to job performance, the influence that outsourcing has had on the amount of time IS managers dedicate to their various tasks (Gonzales, et al., 2010). Outsourcing has generally had little direct influence on the time IS managers need to carry out their activities, although a redistribution of that time has taken place. Indeed, it is easy to see that more time is needed for external relations. Conversely, less time is needed for internal relations because the number of tasks coordinated within the firm itself and within the actual department is considerably smaller. The potential impacts that outsourcing places on an IS manager's working post is generally positive, as many managers feel that their job has acquired more added value because they have

fewer internal tasks and believe that their work is more valuable. As a result, their employment satisfaction level increases and typically have a higher degree of autonomy. Outsourcing does not mean that the IS manager needs knowledge and skills to a lesser extent; if anything, the IS manager needs them more in order to negotiate good contracts. Except for finance-related knowledge (Jain & Kohli, 2009; Kanninen, Piche, & Mikkonen, 2009; Karjaluo, Jarvenpaa, & Kauppi, (2009), IS outsourcing requires a greater amount of knowledge, as IS managers help provide a communication bridge between their organization and the supplier it terms of negotiations. IT knowledge cannot be neglected since awareness of the services and possibilities provided by IT is essential if managers are to know what is being contracted and what the chances for improvement are needed. Of course, there is always the potential to exploit an outsourced IT service provider as a strategic project partner.

When studying the effect of position outsourcing on this industry in major core areas, there is general consensus that IS outsourcing requires more managerial skills, but less time strategy-related activities; more time systems management, better relations and staff management, sharper tactical management techniques and supportive of more positive work environment (Daim, Basoglu, & Tanoglu, 2010; Daramola, Oladipupo, & Musa, 2010; Dominic, Goh, Wong, & Chen, 2010). Obviously, smaller firms in terms of number of workers and sales volume generally have smaller IS departments while focus for IS managers in the larger enterprises was to improve their performance rather than reduce their workload (Gonzales, et al., 2010). It was found that the service sector and the IT-intensive service sector are the most sophisticated in terms of their IS, which is why they exploit the advantages of outsourcing either to liberate work or to enrich the job, but they never see outsourcing as an "enemy" that might impoverish and damage the IS manager's working post (Gonzales, et al., 2010).

Outsourcing Trends

The growing movement toward outsourcing IT departments reveals several trends with IT-intensive industries (Kim & Tadisina, 2010; Marthandan & Tang, 2010). Many companies are utilizing a global sourcing approach to offshoring IT. This global model involves a number of geographically dispersed groups of IT professionals working closely together and allows project work to continue through many time zones. An internal team works to set requirements and specifications, a third-party team in the same time zone works on development, and offshore personnel perform a variety of functions at a fraction of domestic costs. The 24/7 approach is working especially well for companies who invest heavily in new project developments. A globalization model allows companies to respond quickly to opportunities. The added time and risk of hiring people for new development work is less of a consideration and the initial design work is typically less costly with this type of arrangement. An onshore/offshore outsourcing model is being utilized by many companies who allocate most of their standardized and routine activities. This practice enables IT departments to better utilize in-house development teams to focus on expanding capabilities and achieving better results from their systems.

Multisourcing involves utilizing multiple IT service providers in many countries to achieve goals. Companies try to find the best skills at the best price regardless of function or geographic location. EDS, for example, in their Best Shore service program, work can be performed at over 16 IT facilities in 11 countries (King, 2003). A broader range of services is now available throughout the IT outsourcing landscape. One of the newer segments offered is business process outsourcing (BPO). Offshore providers have typically expanded their services to include human resource, accounting and finance capabilities. Interestingly, such mandate industry specific services (e.g., processing for meter reading in the utility companies) have emerged in a trend

that is referred to as “the industrialization of IT.” The ability of an outsourcing partner to process standardized transactions on a global basis is being applied to many industries including credit card and airline electronic transactions.

Another expansion of services, IT-service providers are even branching off into consulting and training. India-based Wipro, offers consulting services that focuses on training software development (King, 2003). A recent emerging trend in IT outsourcing is offshore handoffs. This involves large mature offshore outsourcing vendors, especially in India, subcontracting work to lower cost markets like China and Vietnam. This allows outsourcing vendors to be able to perform services in a way that will enable them to achieve the greatest economies of scale and, thereby, provide the lowest cost to the user. Infrastructure services such as help desk and desktop support are fast growing segments of outsourcing. An increasingly vital function within this segment is network monitoring. Maintaining a secure environment for both the company and its customers is critical to the IT outsourcing relationship (Jensen, 2004).

Undoubtedly, offshoring of IT-intensive services has increased demand for IT management professionals. The need for IT professionals with project management skills is important to the success of outsourcing projects. Many emerging opportunities in IT are for professionals who can work with customers to translate business requirements into technical specifications and work with the outsourcer on implementation. IT professionals, in an outsourcing environment, should have managerial expertise, significant business process knowledge and be skilled in contract negotiating, compliance monitoring as well as accounting and finance (Jain & Kohli, 2009; Kanninen, et al., 2009; Karjalainen, et al., 2009).

This reshuffling of more traditional IT roles is a trend companies should address when designing their outsourcing strategies. Having quality in-house personnel with the abilities to interact effectively with outsourcing partners is integral in fostering successful offshore relationships. The

need for IT professionals to broaden their skills into management is an important trend to consider for human resource departments and individuals in the domestic IT field. Generally, outsourcing has enabled the virtual corporation, a lean organization that performs the functions of planning, collaboration and money management (Browning & Heath, 2009; Cavaleri, 2008; Coates, 2005). The outsourcing of IT is just another inevitability in a highly competitive global environment.

BACKGROUND

Benefits of IT Outsourcing

The economic and political climate in the U.S. is constantly changing, both in terms of governmental support for economic development and closing loop holes for tax inversions (i.e., moving corporate headquarters overseas to take advantage of lower corporate taxes). The U.S. Federal Reserve's recent announcement that it will extend Operation Twist by buying an extra US\$267 billion of long-term Treasury bonds over the next six months (Project Syndicate, 2012). Even though this governmental action is to help the economic recovery, after expanding the monetary policy, the level of GDP is still just about 1% higher than it was nearly several years ago. On September 16, 2011, the U.S. enacted landmark patent legislation. As a result of the Leahy-Smith America Invents Act (AIA) the patent law of the United State will experience the most widespread changes since the initial patent status was first passed in 1790. (Gene, 2012) The primary reason organizations state for outsourcing IT services is improved financial well-being. In general, firms seek to reduce costs, up to 50% or more, and to free up additional capital that can be invested in other segments; overall outsourcing IT has several financial benefits. One benefit of outsourcing IT is that firms are able to concentrate on their competitive advantage and value adding activities. In recent years the specialized firms that offer IT outsourcing services have been able

to increase their capacity and intelligence in the IT field. These firms are now offering a higher quality of service to their customers. A second benefit of outsourcing IT is that the practice provides a company with a global presence that can be beneficial in today's expanding business environment. Firms open themselves up to multiple opportunities by electing to outsource IT (Younies, Barhem, & Hsu, (2007). Firms are able to cut operating costs, shift their focus onto their core activities, provide a higher quality of service to their employees and customers, and establish a presence in the global business environment.

Research estimates that U.S. companies would save up to US\$11 billion in 2004 by outsourcing IT to India. The U.S. banking industry alone has saved US\$6 billion to US\$8 billion annually by outsourcing IT to India. In addition to these savings, it has been reported that India would purchase US\$3 billion worth of high tech equipment from the U.S. due to the outsourcing contracts (Pfannenstien & Tsai, 2004). Management can realize significant financial gains through the sale of industry specific equipment required to perform IT services at established standards. Cost savings and new sales are translated into debt reduction and/or expansion by practicing firms (Hall & Liedtka, 2005).

Outsourcing IT has been shown to stimulate growth in the U.S. economy contrary to popular belief. The above-mentioned corporate benefits have had a direct correlation on price for consumers. India's National Association of Software and Services Companies, Nasscom, commissioned a report by Evaluserve, which found that for every US\$100 worth of work sent abroad by U.S. companies, US\$130 to US\$145 would be reinvested in the U.S. economy. In a study performed by the Institute for International Economics in Washington, Catherine L. Mann found that because of outsourcing, IT hardware is 10 to 30% less expensive (Erber and Sayed-Ahmed, p.110). "A McKinsey study found that two thirds of the economic benefit from sending jobs offshore flows back to the

Figure 1. Offshoring and outsourcing of IT industry, adapted from Erber and Sayed-Ahmed (2005)

U.S. in the form of lower prices” (Pfannenstien & Tsai, 2004, p.78).

Financial benefits are felt locally as firms are utilizing the fiscal freedom they receive from outsourcing IT. Companies can leverage the benefits that outsourcing provides when negotiating contracts with firms within their own country. For example, hourly rates in Asia and other emerging markets are anywhere from 30 to 75% lower than they are in the U.S. In Figure 1 Siemen’s has compared the costs of software engineers in different countries. Based on the information provided in Figure 1, companies from the U.S. and Germany can threaten to go to India or Romania if they feel they are not getting a good enough deal at home for IT services.

Initially, cost savings and financial benefits were the primary purpose of outsourcing IT. However outsourcing IT has evolved into one of the most preferred techniques for restructuring a company. Outsourcing in general has allowed companies to shift their focus and concentration onto their core value adding activities. Outsourcing has provided corporations the opportunity to reduce sunk costs in fixed investments. Initially, outsourcing work and payments to lower cost countries can reduce fixed R&D outlays. The “substitution of fixed costs by variable costs gives the outsourcing company greater flexibility in

reallocating its capital” (Erber & Sayed-Ahmed, 2005, p.102). A study in the McKinsey Quarterly found that the U.S. economy has benefited from IT outsourcing because the money saved by outsourcing IT creates new jobs, or as the study puts it redeployed labor (Erber & Sayed-Ahmed, 2005).

The importance of the IT department within a company cannot be ignored. As Hall and Liedtka (2005, p. 200) stated, “A successful IT function contributes significantly to the operating efficiency of a firm.” In 2000 a reported survey found that 25 of the 36 major firms that have achieved level five maturity of the Software Capability Maturity Model (CMM) were located in India. The other 11 were located in the U.S, but were suppliers to the government and were not available to the commercial software market (Pfannenstien & Tsai, 2004). China has been known for years for the “China price” in manufacturing and now India has the “India price” in IT (King, 2005). India has proved that they are highly skilled in the IT field and are able to offer a cheaper rate than most domestic firms as confirmed by the fact that India contains approximately 70% of the level five CMMs in the world.

In today’s business environment having a global presence is a necessity for a firm to survive; and outsourcing provides that presence to

companies. Certain companies have come to the realization that allocating resources offshore through outsourcing is necessary for them to maintain competitiveness in a global economy (Kanninen, Piche, & Mikkonen, 2009; Karjalainen, Jarvenpaa, & Kauppi, 2009; Pfannestien & Tsai, 2004). It is believed that if a company resists the temptation to outsource now they will be hurting their ability to compete globally in the future. Whether it is IT or another related activity, outsourcing provides a company with knowledge and insight into other cultures, which can play a significant role in future decisions and determining future successes or failures.

Risks of Outsourcing IT

There are several risks that company's face today when attempting to outsource information technology to a vendor company. One of most obvious major risk is capability; or how well the vendor can effectively achieve the goals and objectives of the client. Outsourcing projects often have a geographical separation between the two companies, which can cause communication problems. The vendor company might lose focus of the actual goals and objectives are of the client company. A number of researchers have discussed this phenomenon and have suggested that complexity and chaos can easily cause activities to stray from requirements or specifications, resulting in product or service failure. Some of this failure results from expanding or deviating from the original concept, goal, or purpose of the project to be outsourced. Activities such as change requests and the prioritization of the changes may cause the scope of the operations for both companies to alter significantly (Rasolinezhad, 2009; Sakkthivel, 2009). If the scope of the project changes then it is possible for the vendor to lose focus on the overall objectives. The consequences for losing focus of the client's objectives could be disastrous for everyone involved.

Another important risk that is associated with outsourcing is the inability for the client company to maintain security of their technology information (Smith, Smith, Gopalakrishna-Remani, & Offodile, 2012; Smith, 2005; Smith & Lias, (2005). The client should be aware of the ability of the vendor to develop technology that could compromise the security of their information. International laws that regulate the sharing of information make it possible for the vendor company to take sensitive information and provide it to their clients' competitors. Several foreign countries do not have laws that prohibit such sharing of confidential information. This could cost the client an unnecessary amount of problems. For example, the client company could suffer a multitude of losses from customer trust to legal fees. Ultimately, it is important for the client company to maintain their own information security.

A vendor firm could possibly be performing technology outsourcing for industry competitors. Client information could be used against them or leaked to their competitors. Vendors may become capable of integrating forward; developing from a partner to a competitor. Once a vendor is able to procure technology they could enter the market and use it to take business from the client. Management should be willing to take these risks into consideration. Typically firms entering into an outsourcing relationship require that the vendor sign a non-competitive agreement that would prevent them from using their information in any way other than to perform IT services for the client. It can be difficult for companies to enforce breach of contract penalties or fines because of certain international regulations.

Companies engaging in outsourcing should take into account the possibility that the vendor will lose control over project. Loss of control by the vendor could result in complete chaos within the client firm. Parker and Russell (2004) suggested that this possibility can be reduced through "clear responsibilities and clear decision processes and procedures, combined with the formal, regulatory

controls and the more informal social controls can prevent process failures” (p. 60). It is important for managers of the client company to provide specific guidelines and objectives for the vendor to follow to prevent this chaos from occurring. By providing specific guidelines management can predict how the vendor will handle the technology process.

Companies looking to outsource IT face the risk that a vendor lacks experience in dealing with cutting edge information technology. Because there are low barriers to entry for new companies to perform outsourcing activities it is easy for a vendor with little experience to compete for large outsourcing contracts. Appropriate research by management is required to ensure that the vendor can handle the contract. “Even though a firm competes in the field of information technology, there is no guarantee that they are qualified to manage an outsourcing contract” (Sullivan & Ngwenyama, 2005, p.76). Management should verify that the vendor can perform the specific task that they want done. Even though a vendor has experience performing IT services it does not mean that the vendor has experience in what the client wants done. The research process should be in depth enough to reveal the number of experienced and qualified employees that the vendor has employed. A large outsourcing requirement would overburden a vendor, which has only a limited number of experienced employees to perform the service. It is essential for management to investigate these issues before awarding an outsourcing contract.

Client/vendor compatibility is another risk that executives should consider when collaborating on an outsourcing project. “For organizations to work together, it is imperative that there be some degree of cultural fit and compatibility” (Piachaud, 2005, p. 42). Compatibility can occur on several different levels. First, the cultures of both companies play an important role in the success of the project. If the culture of the client and vendor are not similar it is possible to lose focus on what the vendor is trying to accomplish. Second is the service attitude of the client company versus that of the vendor. If the client company is used to providing exceptional

service to their customers and the vendor is not capable of providing that same service then the client could potentially lose customers through poor service. The third level of compatibility is the long-term strategic fit of both companies. The vendor company should be willing to adapt and change according to how the client changes their long-term strategic goals. Since projects can span over several years it is possible that the strategic plans of the client may change throughout the duration of the contract. The vendor needs to be capable of changing along with their client.

Another important risk factor that is associated with outsourcing is the cost of making the decision to have a vendor provide information technology that you cannot provide on your own (Karlsson, 2003; Riis, Johansen, Waehrens, & Englyst, 2007). Typically, many companies outsource to save money. However, there are transaction costs that the outsourcing company needs to be aware of before making this decision. Transaction costs can be anything that is associated with making the outsourcing project happen. “Transaction costs can include setup costs, redeployment or relocation costs, sales tax on equipment or purchases, and leasing costs” (Bahli & Rivard, 2003, p.214). It is difficult to put a dollar value on some of these transaction costs, which makes it a very important aspect for management to consider before making any decisions.

Management plays the most important role in reducing the risks associated with outsourcing any type of project. It is clearly the managers of the client company’s responsibility to effectively motivate and communicate with their employees and with the vendor company. It is management’s fundamental responsibility to understand how the outsourcing process and set up the correct agreement with the vendor. Management needs to understand what can happen, how likely it will occur, and what will be the consequences if it happens when dealing with project risk. Ultimately the executives of the client company are going to be held responsible for any loss that occurs. They are going to have to explain to their shareholders

why outsourcing of their information technology failed; causing them to lose money and potentially customers.

MAIN FOCUS OF THE ARTICLE

Transaction Processing

Companies have been outsourcing information technology as far back as 1962, when EDS, started a technology revolution that is still going strong today. IT and outsourcing is a US\$680 billion global industry. EDS started as a US\$1000 investment and has grown into a US\$20+ billion technology services industry leader. Their IT services have grown to include systems management, systems integration, centralized transaction processing and as the world's largest private digital voice, data and video network. In 1963 Frito Lay became the first firm to sign a five-year agreement with EDS in facilities management. By signing this long-term agreement, EDS was given a more financially secure future. Over the next several years EDS entered into several contracts with medical firms who were outsourcing data processing of medical records. Among the firms signing with EDS were Medicaid in Texas and Blue Shield of California. EDS continues to maintain a long-term relationship with Blue Shield to become a US\$1 million-a-month contract.

In 1975 EDS began looking beyond the United States for contracts in outsourcing. Saudi Arabia, Singapore, Iran, and Pakistan were among the first countries where EDS outsourced information technology. Over the next several years, EDS continued to perform outsourcing for several companies. In 1986 EDS was sold to General Motors. GM expanded the operations of EDS to include projects in Latin America, France, and Japan. In 1987 (on EDS's 25th anniversary) this US\$1000 investment company became a US\$4.4 billion revenue company with operations in computers and communications throughout the world.

The 1990s showed more of the same with companies like Continental Airlines Holding Inc. and Saab in Sweden signing contracts for computer and communications facilities and systems management, respectively. These contracts brought in billions of dollars for long-term operations. 1992 revenues were US\$8.2 billion and EDS was working with GE MasterCard, Blue Cross Blue Shield, and purchasing firms in Germany in the IT services industry. In 2000 EDS won a government contract for information technology to develop and manage the Navy Marine Corps Intranet (NMCI).

EDS has over 65,000 servers and supports 2.5 million desktops globally. It has 350 million customer relationships and interacts with 2.4 billion customers in 48 languages. As its website states, EDS provides the best solutions for executives to maximize return on their IT investments. Its annual revenues today are over US\$20 billion. Currently EDS is the second largest information technology provider in the world.

Over the years several other firms have entered into the industry of information technology outsourcing. Cisco Systems was started in 1984 and is considered a worldwide leader in networking of the Internet. In 2002 Cisco Systems and SBC signed a 3-½ year contract that would lead to many outsourcing projects between the two firms. Cisco provides the networking equipment and SBC assists clients through the construction and management of networks for other companies in the telephone industry (Berniker, p.1). In 2004-2005 Cisco and EDS joined forces to develop a new model to help customers manage information technology resources. Cisco is providing networking expertise to gain new customers and insight into outsourcing and data center markets along with EDS's global presence (Waltner, 2005).

IBM is another company who uses strategic outsourcing services to manage information technology systems. IBM does this through transfer of IT employees and IT assets from companies. In order to gain the trust of companies, IBM works

with the customers through case studies, executive reports and videos to give them an understanding of all that is involved in outsourcing. IBM's employees are strategic partners with clients – they work with the customers to provide tools, processes and methods that best suit each customers' needs. In 2002, for example, IBM Global Services, the world's largest information technology services and consulting provider made over US\$36 billion in revenues. In 2003, for example, IBM was the leader in the European market of IT outsourcing, signing 11 of the 100 top outsourcing deals on the continent. By managing the customers' IT applications and business processes through IBM, customers have become more effective, productive, and saved money. Undoubtedly, it is the potential for the IT services vendor to be a project partner or collaborator with the procuring organization, in the form of a strategic contracting alliance. In this case, goods and services may be traded as "in-kind" transactions, with potential win-win cost savings. Risks still apply of course.

Outsourcing allows firms to structure their focuses on core products with the knowledge that the non-core projects are well managed. Other outsourcing companies include UNISYS, which uses IT outsourcing (ITO), business process outsourcing (BPO), and technology support and maintenance services to deliver information technology to its customers. Hp Invent offers strategic outsourcing with over 800 contracts globally. Acxiom provides IT outsourcing services to Fortune 1000 companies, who gain benefits in cost advantages and technology to gain competitive advantage. SAP, a German-based outsourcing company, offers solutions, services, and partnerships to ensure that business process outsourcing (BPO) can give the best results. The main theme behind all of these companies is the following: reduce risks, lower costs, and improve process quality.

Outsourcing Prospects

By most transactional accounts and processing evidence, outsourcing IT services appears to be a major operational decision supported by most global corporations. Companies can no longer ignore the benefits of outsourcing IT as they compete in an increasing competitive global market. McKinsey and Co suggested that in 2008 IT outsourcing was over a US\$57 billion annual export industry and that over 4 million people will be employed in India through international outsourcing. Forrester predicted that IT jobs overseas will rise from 27,000 in 2000 to over 109,000 in 2005 (Pfannenstien & Tsai, 2004). And U.S. companies have only started to explore outsourcing IT services on a global level since the early 1990s. Companies continue to learn about the process and are adapting to the problems they have experienced with outsourcing IT services as the process is still in the early stages of development.

In recent years companies have learned through experiences to shorten contract length with suppliers and include certain clauses in the contracts; such as performance measures. As companies continue to outsource IT services, they will have to continue to adapt to the problems they have experienced. For example King suggested that companies will have to require that their IT employees have the softer skills of business in the future. Traditionally, some IT employees lack the people skills or softer skills in business (Karls-son, 2003; Riis, et al., 2007). However, as King (2005) suggested, many companies will need to require their employees to have the softer skills of business. The development of the softer skills associated with business provide employees with the ability to interact with others, enhances negotiation techniques, and develops trust between partners, all of which will be critical if companies are going to grow on a global level.

FUTURE RESEARCH DIRECTIONS

There has been many research studies on the advantages and a disadvantages associated with outsourcing/offshoring as previously detailed in this chapter. According to Wee, Peng, and Wee (2010), the capital or employee size of a corporation does not affect whether or not an organization decides to outsource. Therefore, outsourcing and offshoring activities are not just for large corporations with huge cash reserves, it has filtered down to many players, regardless of size and influence. The authors the present study have found this statistic interesting and an issue to take into consideration the level of capital their respective organizations before making a decision. As more research matures in this area and more applications of financial and operational analytics come to play in discussing the ultimate benefits and costs of outsourcing/offshoring activities to a firm, industry, and/or nation, the future holds great promise for this area as an academic discipline. Undoubtedly, there are many different outsourcing techniques vary from different types of industries. For instance, automobile industries utilize different outsourcing strategies than the computer industry. The concepts of supplier collaboration and integration issues alone would be great areas to research. As previous discussed, there is a risk for supplier partners not to be generally satisfied with their related organizations as they feel that management may put an over emphasis on profit. Keeping their supplier satisfaction is a major key in creating a good outsourcing practice and beyond the scope of the present study.

CONCLUSION

Research in the present study has demonstrated that outsourcing in its various forms can be successfully applied to service jobs as well as manufacturing. The traditional thought is that

manufacturing has moved overseas to save in labor costs, but the more traditional service firms could not make that transition. However, the recent trend in IT-related offshoring/outsourcing has laid that claim to rest. In fact, it is possible and that any industry in the future can be and probably will be outsourced. IT outsourcing has recently become a lightning rod for controversy, but our research indicates that outsourcing has become an integral part of the domestic economy. Not only domestically, global firms now deeply depend upon the cost saving attributes of outsourcing/offshoring. Consumers have come to expect the cheaper products and services that have been made available through outsourcing. Therefore, as many cost sensitive consumers globally would gladly state, we welcome the further development of outsourcing strategies.

ACKNOWLEDGMENT

The authors wish to acknowledge the valuable contributions of the reviewers for their input into the final chapter.

KEY TERMS AND DEFINITIONS

Business Process Outsourcing (BPO): BPO is a generic term that has determine meaning in different contexts. It may be considered a type of

offshoring/outsourcing that deals primarily with the contracting of the operational aspects, management, duties, and legal and ethical responsibilities of a specific business process to third-party service providers.

Multisourcing: Refers to a very basic type of outsourcing approach in which IT operations and technology infrastructure are typically subcontracted to multiple vendors as opposed to a single or small set of vendors or service providers.

Outsourcing: It is a broad-based term that describes the procuring of goods or services that are needed by a business under contract with an external supplier. A literal definition would involve any form of trade done outside the firm as outsourcing.

Offshore Handoffs: When the process of formally charging an offshore or outsourcer with the contractual obligations, the host organization has to clearly identify what the responsibilities and expectations of onshore and offshore communication links and interactions. Such activities ensure that clearly defined service levels for each

functional area are outlined in the detail that will allow for better monitoring and updates among all locations.

Offshoring: Offshore and its related outsourcing describes the practice of contracting to outside vendors in another country, in which the client company has no direct ownership. This low cost, expansion in number and increased capability of global vendors has many important benefits and risks associated with such practices.

Service Quality: A long-term strategy that tries to differentiate a firm's products or services by assessing of how well a delivered customer service meets or exceeds a client's expectations of that good or service.

Tax Inversion: A tax inversion is basically a strategy where a domestic firm establishes or buys another company in a country with a lower corporate tax rate. Once this relocation of global headquarters is completed, the newly founded firm can avoid paying the higher tax rate in the formal host country, even if most of its sales and profit are derived in another country.

INTRODUCTION

For the purpose of meeting customer requirements logistics management is defined as the process of effective and efficient flow and storing, bringing under control and planning of movement of all kinds of product, service and information flow from starting point of the raw material to the final point of product's consumption in the supply chain (Cooper et al., 1997). The firms that are active in logistics field which has presently become a very important sector have been operating within difficult market conditions and intense competition environment. In order to maintain their existence under these conditions logistics firms must present their products and services to the market and their customers faster and in a more economical way than their competitors. In order to decrease supply time duration and provide fast response to demand changes that takes place in task durations in logistics, sector product information need to be obtained in real time. For this reason, firms need application techniques that decrease the costs and increase the efficiency and performance in logistics sector. Radio frequency Identification (RFID) is an automatic identification technology use of which has been gradually increasing in supply chain management.

Operations in logistics management are basically formed by the two processes; product and information mobility. When products are on the move which is during transportation, distribution and handling activities process product related information need to be rapidly identified and passed onto related departments, as well. The warehouses, which are used for product stocking in logistic, are places where product handling and physical movements are carried out intensively. Besides warehouse management is an important task in logistic from the point of bringing down the costs and reaching customer satisfaction. Today system control and management of warehouses that contain many products is difficult without having automatic identification. For example barcode technology that was started to be used in inventory controlling activities after 1990s has decreased erroneous and insufficient data entry that can take place due to human mistakes and allowed significant efficiency and performance increase. At present however, the RFID has superior advantages compared to barcode technology. So this technology allows for easily tracking of business processes, decreasing of labor costs and increasing of effectiveness of logistics and supply chain (Xiao et al., 2007).

Figure 1. RFID System Components

This article aims at design and application of a tracking system with RFID in response to the problem of pricing of activities of forklifts used in handling operations in logistics warehouse management. The rest of the study has been organized as follows: In the second section basic definitions and general information for RFID have been briefly given. In the third section the literature review encompassing the studies about RFID has been presented. In the fourth section problems dealt with in the application have been identified. In the fifth section structure of the designed RFID system has been explained. In the case study, pricing of movements of forklifts via designed system has been explained by an example. In the fifth section results of the study have been given and useful findings that could be drawn from system have been identified. The study has been ended with the conclusion section.

BACKGROUND

RFID is an object identification technology that uses radio frequency without any help from a human. Although this technology was found out in 1950s its real development and application have been widely spread after 1990 (Roberts, 2006). Basically RFID system is made up of a microchip (tag) around which there is wrapped antenna and a reader. Data and energy transfers are facilitated without having a physical contact between microchip and the reader (Zhang et al.,

2006). The most distinguishing advantage of the RFID systems is that unlike barcode systems its technology does not require a contact and line sight (Delen et al., 2007). As it is seen in Figure 1 an RFID system is made up of items like RFID tag, antenna, reader, controller and software that will facilitate the communications between this hardware as well as a database that will keep the data coming out as a result of this (Maloni and DeWolf, 2006).

When the literature is analyzed it is seen that RFID related studies have been conducted in two groups as academic and practical studies (Sarac et al., 2010). These studies have concentrated on warehouse related system components like RFID tag, reader and antenna. Ukkonen et al. (2004) have proposed a passive RFID antenna for metallic objects. In order to measure tag performance used in RFID technology Flores et al. (2005) have presented a simple method which was based on experimental and laboratory measurements.

The studies in recent years however have concentrated on RFID's applications in various fields such as logistics management, library and factory automation. In their wide-ranging research that identifies present day RFID applications Zhu et al. (2012) have presented a detailed analysis related to fields where RFID was used. Wang et al. (2007) have made the design of dynamic RFID based supply chain control and management system for construction industry. They have applied their proposed model to a factory that manufactures high-tech materials for construction industry in

Taiwan. For a pilot project initiated by Taiwan government Hong et al. (2011) have developed a financially feasible food tracking system with RFID. They have tried the system they developed at a markets chain company in Taiwan through a case study. In order to track the owned medical assets Öztekin et al. (2010) have shown that it is possible to apply RFID system in hospitals and to set up an effective and efficient medical asset tracking system. By conducting a simulation study LegoRobot and LabVIEW Elshayeb et al. (2010) proved that in all phases of supply chains of small and medium sized firms in retail sector products can be identified in real time and in a more effective way by RFID technology. In their article Björk et al. (2011) have explained the new RFID technology and tracking solutions that they developed for tree and forestry production industry. Hou et al. (2011) have developed a RFID based shopping tracking algorithm that would solve the problem customers experience to learn the price and to find the product particularly at large markets. Aubert (2011) has conducted a study particularly related to control and tracking with RFID of implanted devices on people with biological functional deficiencies.

While many of the previous studies have concentrated on tracking and identification of RFID tag information, today there is an increasing demand for automatic recognition systems with RFID as a solution to the problems emerging in internal and external processes of logistics enterprises. In their article Ngai et al. (2007) have presented findings of the case study they conducted at a container warehouse to track the places of containers and stackers. In order to transfer container and stacker vehicle information from RFID reader to main computer system they developed a prototype RFID system that was integrated to mobile commerce. Ergen et al. (2007) have made a study that facilitated controlling of supply chain management of the prefabricated materials used in construction sector as well as in job-order sector with the use of RFID and they achieved tracking of stocking, transportation and

assembly of the products. Dabbene et al. (2016) used RFID for food traceability and reported their implementation results in a particular food supply chain such as meat, cheese, fish, vegetables and plants. Chongwatpol and Sharda, (2013) assessed the RFID deployment to a manufacturing service provider company for tracing components on its production line. After the RFID deployment, the cycle time, machine utilizations, and penalty costs are significantly improved when it is compared to traditional approach. Feng et. al (2013) developed a cattle/beef traceability system that integrated RFID technology with PDA and barcode printer to provide accurate traceability information. They evaluated and optimized their system in a sample supply chain. Velandia et. al (2016) used RFID for automatic identification system in a crankshaft manufacturing domain. In their study they investigated the feasibility of implementing RFID system for manufacturing and assembly of crankshafts. As a result when the previous studies in the literature are analyzed, specifically there is no prior research that attempted to understand the adoption of RFID technologies in warehouse management for pricing of forklift operations. This study attempts to fill this gap.

RFID AND WAREHOUSE MANAGEMENT

Warehousing operations that require effective product mobility have an important place in logistics processes and they are the most costly processes in warehouse management. Besides, with respect to product features and structure of the sector requirements of the firms for warehousing operations change and it affects warehousing costs as well. Therefore for a successful warehouse management, when stocking the goods and transferring them from the warehouse to the required places, saving time, energy and cost is necessary. Nowadays strategic role of the warehouse has been changing, too. Previously, warehouses were used only to keep the goods but now product variety

and number of competitors are high in market, so warehouses are being operated as consolidation points that add strategic values to logistics and supply chain. Freese (2000) has stated this changing role of warehouse with the statement “Operational costs have been increasing faster than outputs of the process”. A warehouse management system provides the information necessary to manage and control the flow in the warehouse from accepting the goods to delivery. Donath et al. (2002) have pointed out that facilitating the traceability of products and instruments by using automatic definition systems like RFID particularly in warehouse management as a very important subject matter that should be taken into account.

The activities like loading, unloading and transfer that take place in warehouse management processes are called handling activities. These activities are the activities that do not add value to the final product but are the essential ones for the continuation of warehousing operations. In order to carry out these activities vehicles such as forklift (stacking), order picker and load carrier are needed. Heragu (2008) and Raman et al. (2009) have stated that forklifts are the most important instruments that allow fast and low cost handling of materials in warehouse management. Effective and efficient use of forklifts in handling activities affects warehouse management performance significantly. By using RFID for forklift tracking system, the cost of business processes can be reduced. In other words, by tracking forklift movements, real time, accurate and up to date information that is needed by the managers to determine warehouse costs can be obtained. Logistics firms can decrease their operational costs and increase service quality by this way.

PROBLEM STATEMENT

For this study, a real problem is obtained from a logistic firm. It is the leader of Turkish logistic sector. In addition to domestic and international transportation services, it has also been providing

warehousing services to its customers. The firm has been performing these services as follows: It has been renting out certain areas of the warehouses it owns to the firms that want to get warehousing service. The firms renting the warehouse space have been buying all types of operational level logistics services that are needed during warehousing from the logistic firm as well.

In practice, forklifts are rented on daily basis, not hourly basis because of economic reasons. So the logistic firm wants to measure and invoice the handlings service it provides to tenants. To put it another way, it aims to determine whether logistics services performed for two different warehouse spaces with the same size rented out to two different firms at the same unit price are the same or not from the cost perspective. In addition to unit space price the firm was determining the price of logistics services it would render to customers intuitively without making any measurements only using daily price of forklifts (for 24 hours). This situation resulted the fact that two firms renting the same size warehouse to pay the same amount of warehousing price provided that one of the firms is getting more logistics service than the other. As a result, the warehouse managers have decided to change this unfair pricing policy.

After the meetings held with warehouse managers' authors of this article have stated that this problem could be solved by a vehicle tracking system with RFID. For this purpose, firstly the pricing policy that the logistics firm would provide to its customers in warehousing field has been changed in a way that it takes the two criteria (fixed and variable costs) into account. As it is known from economics, if we assume that price quantity relation for a good is linear, the total cost is stated as the sum of fixed cost and variable cost as shown below:

$$y = a + bx \quad (1)$$

Where a shows fixed cost which means monthly or annual rent of the warehouse, x indicates the production amount which means forklift total operation time, b shows the cost per

Table 1. Equipment specification

Equipment	Brand	Specification	Quantity
Fixed Reader-UHF (Motorola FX7400)	Motorola	FX7400 UHF	2
Antenna	LAIRD	S8658 PL UHF (Dairesel polarizasyonlu)	4
Active RFID tag	Motorola	Confidex Survivor UHF	4
Computer for web and database server	Dell	With user interface	1

unit produced, in other words unit (hourly/daily) working cost of the forklift. Firstly, warehouse rent which constitutes the fixed cost is calculated as below:

Fixed cost = rented warehouse space x rent price per square meter x rental duration (2)

In the second step forklift movements that take place during products are stored in the warehouse and constituent variable costs (bx) need to be priced. The type of the forklift used in handling operation changes with respect to characteristics of raw material, intermediate good or product to be carried. Besides hourly working prices of forklifts differ with respect to forklift type and forklift carrying capacity. Accordingly, with respect to forklift's time spent for logistics services and used forklift's hourly price the variable cost is calculated as follows:

Variable Cost= Forklift operation time (hour) x forklift's hourly working price (3)

As a result, by real time tracking the forklifts with RFID system the following formula has been developed to determine price of operations.

$$TC = a + \sum_{i=1}^n F_j \left(\sum_j^m t_{ij}^{exit_time} - t_{ij}^{entrance_time} \right) \quad (4)$$

In this formula TC denotes total costs

$a = s \cdot r \cdot p$; (' s ' rented warehouse space, ' r ' warehouse's rent per square meter, ' p ' rental period) show the fixed costs;

F_j forklift's hourly working price
 $j = 1, 2, \dots, m$ denotes forklift number used in carrying operation.
 $t_{ij}^{entrance_time}$ j . forklift's entrance time to i . warehouse

$t_{ij}^{exit_time}$ j . forklift's exit time from i . warehouse

$\sum_{i=1}^n F_j \left(\sum_j^m t_{ij}^{exit_time} - t_{ij}^{entrance_time} \right)$ formula states variable costs, $i = 1, 2, \dots, n$ denotes warehouse number

INTRODUCTION TO DEVELOPED FORKLIFT TRACKING SYSTEM

Application of forklift tracking system that was developed as a solution for the problem defined in the previous section has been made at the logistics firm's facility in Istanbul. For the experimental design the sections where products belonging to small kitchen appliances, house cleaning, personal and baby care products company (section A) and professional cleaning and sanitation systems support firm (section B) were selected. Forklift tracking system is made up of RFID UHF tags compatible with EPC code, reader, input/output antennas, a computer with developed forklift tracking software and a database system. Information about the hardware used in system design is presented in Table 1 and schematic representation of the used hardware in the warehouse is presented in Figure 2.

Figure 2. Schematic visualization of warehouses where application has been made

The active RFID tag used in tracking system makes real time information transfer to RFID reader about the location where the forklift is at. RFID tag in-built to forklifts sends a signal every 5 seconds for the location it is at. This signal is processed by RFID reader and with the help of developed software, entrance to and exit from warehouse information is recorded to the database on date and hour basis according to the signal data coming from the reader forklift. This information is later used in costing of operation times of forklifts used in the warehouse. In the photos

given in Figure 3 and Figure 4 two different views of the warehouse where forklift tracking system with RFID was applied is given. As seen from these photos antenna-I and antenna-II have been erected 110 cm above from the ground. Forklifts' entrance to and exit from warehouses are being controlled by these antennas. For this purpose, antenna number I in sections A and B is addressed as entrance antenna and antenna number II is addressed as the exit antenna. Similar design used in section A is made for section B section, as well.

Figure 3. System that was set up in application

Figure 4. RFID antennas used in application

RFID reader however was placed 90 cm above from the ground between entrance-exit antennas and it was connected to the computer system in the local network (Figure 5).

Four forklifts were used in the experimental study and RFID UHF tags were erected at the back of each forklift's driver seat as seen in Figure 6 and association between forklift and tag was done as shown in Table 2.

Figure 5. RFID UHF reader used in the application

FORKLIFT TRACKING SOFTWARE

A software has been developed for forklift movement tracking. The forklift entrance-exit tracking algorithm used in the software functions as follows: Entrance or exit decision to either section A or section B of any forklift is given through sensing by both RFID antennas (Antenna I and Antenna II) of forklift tag. Any forklift's entrance decision

Figure 6. RFID tag used in application

Table 2. Association between tag and forklift

Forklift Tag ID	Forklift Serial Number	Forklift License Plate
01	14829	34 BITS 34
02	14825	34 BITS 35
03	16947	34 BITS 36
04	14826	34 BITS 37

to any warehouse section is given upon sensing of RFID tag's incoming signal firstly from 1st antenna then from 2nd antenna by RFID reader. Exit decision is just the opposite to entrance operation. The flow chart showing the functioning of the algorithm is presented in Figure 7.

In order to transfer the information coming from RFID tag in real time a wireless network was installed between the RFID reader and the computer system. The data coming from RFID readers are transmitted to a database which is used for storing the forklift movements.

CASE STUDY: PRICING BASED ON REAL-TIME ANALYSIS OF FORKLIFT UTILIZATION

In this section the system designed for price determination is explained by a numerical example. For the numerical example, records of the forklift movements taking place at Section A and Section

Figure 7. The flowchart of the forklift tracking algorithm

Table 3. Rented warehouse information

	Size of Rented Area (m ²)	Price of Per Square Meter (\$/m ²)	Rental Period (Month)
Tenant A	200	20	1
Tenant B	200	20	1

Table 4. Forklift types used and leasing price

Forklift Type	Daily Price of Forklifts (For 24 Hours)
I	\$85.00
II	\$100.00
III	\$65.00
IV	\$25.00

B during one month (for the sake of simplicity rent period has been taken as one month) have been taken into account. Firstly the warehouse information table that consists of information about space rented by firms (in Table 3) and daily leasing price of the forklifts (in Table 4) have been obtained as follows:

Then, the detail information about the warehouse, the forklift and the duration it was in operation was obtained from database records and required tables are created. For example, the forklift operation tables that show forklift type, and total working time used in handling operations for sections A and B (tenants warehouses) is shown in Table 5. The second column shows that the tenant firms rented the forklift types in same duration days. But, the tenant firms just used the forklifts in different operation times. The last

two columns show that total real working time of the forklifts in handling operations measured by RFID system for firm A and firm B respectively.

Finally, by using Table 4, Table 5 and by the help of equation 4 the fixed and variable costs have been calculated. *Fixed cost*: As it can be seen from Table 3 both Section A and Section B firms have rented the same size warehouse space (200 m²). In this case fixed costs are the same for both firms. *Variable costs*: It changes with respect to forklift operation duration and types of the forklift used. Therefore monthly total rent costs of two different firms renting same size warehouse space become different depending on the forklift operation costs. Before and after the RFID forklift tracking system, the handling operations costs were calculated and the results are shown in Table 6.

Table 5. Forklift types used in section A and B for operation times

Forklift Type	Total Rented Time (Days)	Section A	Section B
		Total Operating Time Measured With RFID Tracking System (Minutes)	Total Operating Time Measured With RFID Tracking System (Minutes)
I	5	3600 $\cong$ 2.5 (days)	2400 $\cong$ 1.66 (days)
II	6	4500 $\cong$ 3.125 (days)	3800 $\cong$ 2.63 (days)
III	4	2200 $\cong$ 1.527 (days)	3000 $\cong$ 2.08 (days)
IV	10	6700 $\cong$ 4.652 (days)	7500 $\cong$ 5.20 (days)

Table 6. Total cost calculation table for tenants

	Before RFID		After RFID	
	Fixed Costs	Variable Costs	Fixed Costs	Variable Costs
Tenant A	\$4000	\$1535	\$4000	\$740.5
Tenant B	\$4000	\$1535	\$4000	\$669.3

Figure 8. Forklift tracking report

Vehicle Tracking Report

34 BITS 34

<

As it can be seen from this example operation costs of the firm renting warehouse A has turned out to be higher than that of firm B. Despite the fact that fixed costs are the same for both companies total costs that should be paid differ. The logistic firm which rents its depots will be able to present to its customer more economic offers. This situation will give advantage to the logistic firm according to its competitor.

CONCLUSION

This section describes the computational experiments to evaluate the performance of the proposed system. This study showed two important results

for warehouse managers: Firstly, operations that forklifts perform in warehouses can be tracked in real time by RFID. Besides, from any point within the scope of local network it is possible to reach the network and thanks to web based software it is possible to monitor forklift movements easily. The report samples taken for this purpose are presented in Figure 8 below. In these reports it is possible to see entrance and exit information related to forklifts and it is easy to calculate forklift's operation time depending on this information. For example in the entrance-exit report of forklift with license plate "34 BITS 37" whose Tag ID is 4 there is no information. From this report it is understood that forklift number 4 was not used for any operation.

Its second importance is that it allowed accurate pricing of forklift operations taking place in different warehouses. As it can be seen from the case study forklift operation costs in warehouse A is greater than that of warehouse B. Therefore monthly total rent cost of two different firms renting the same unit space at the same rent price changes with respect to forklift operations. In other words total warehouse rent cost differs depending on variable costs.

FUTURE RESEARCH DIRECTIONS

This paper was aimed at determination of pricing for forklift per utilization time. We developed a forklift tracking method and introduced a well-designed RFID system. To the best of our knowledge, this was the first reported application of RFID to solve the problem under consideration. To determine the forklift operation costs in real time we presented a forklift tracking principle which works with RFID. According to this system the logistics firm provided with a solution to the problem of determining forklift utilization costs for the warehouses rented out to different firms. Besides, thanks to developed forklift tracking software and by the help of reports obtained from data base records warehouse manager can make cost analysis more easily. This study which was conducted in an experimental way has a flexible structure to be used in other units of the firm by making only hardware investments. Experimental results show that RFID, in addition to product tracking in retail and logistics management, can also be successfully used in solving specific problems that the firms have. Preliminary results on the forklift operation cost determination reveal that the proposed system is also effective, yet certain modifications are needed to make it more suitable for the different case. In the future, it is needed studies to take into account the subject for these purposes.

KEY TERMS AND DEFINITIONS

Forklift: It is equipment that can load and upload items for shelving.

RFID: It is a technological device which can be used for item identification and traceability.

Tag: A small piece or part that is attached to an item body.

Warehouse: It is a facility where items are stored in it.

Warehouse Management: It covers many processes in it to be able to control all items, equipments and activities.

Profit Maximizing Network Modeling With Inventory and Capacity Considerations

Tan Miller

Renato de Matta

University of Iowa, USA

INTRODUCTION

Developing integrated strategic, tactical and operational manufacturing and distribution plans for the global supply chain of a large, international firm represents a formidable planning, as well as organizational undertaking. Moreover, to develop and execute plans that are not only *integrated*, but which *maximize profits* on a global basis presents a challenge of far greater magnitude. The use of advanced optimization modeling based analytics can generate keen insights for management decisions regarding sourcing, production, distribution, inventory and demand management on supply chain networks. This includes scenario planning analyses of complex strategic trade-offs such as the optimal balance between inventory levels and reserve manufacturing capacity on a network. The use of these techniques can bring clarity to the complex decisions that make integrated manufacturing and distribution planning both difficult and important (Shapiro 2010).

For purposes of this chapter, we will define “optimization modeling based analytics” as the utilization of mathematical optimization models to provide decision support for supply chain network decisions and management (i.e., models employing linear, mixed integer and nonlinear programming and related heuristic algorithms). Thus, optimization based modeling techniques represent an important component of the overall set of analytic decision support tools that can help facilitate efficient and effective supply chain network planning and management.

In summary, the objectives of this chapter include the following:

1. To review the role of optimization modeling based analytics in supporting a firm’s supply chain planning and management activities,
2. To discuss how mathematical optimization models with profit maximizing objective functions fit into a hierarchical framework for a firm’s supply chain network planning and scheduling processes,
3. To illustrate how optimization models can support key strategic network design decisions such as the appropriate balance between inventory and manufacturing capacity investment,
4. To review why optimization modeling based analytics will continue to play an increasingly important role in supply chain network decision support and management.

BACKGROUND

Supply chain management mathematical optimization models are the optimal tools for analyzing complex supply chain management problems (Shapiro 2010). In this chapter, we will focus on “deterministic” mathematical optimization models where a model solution is driven by an exogenously given (i.e., pre-determined) forecast. We note that in industry practice, the vast majority of optimization models employed are deterministic.

Practitioners typically address the potential limitations of using a single, fixed forecast by running their optimization planning models under multiple forecast scenarios, where often probabilities are assigned to each scenario. This approach alleviates the potential limitations of developing a planning solution based upon just one, deterministic forecast (Shapiro, 2010). Examples of potential uses of advanced optimization based analytics are as follows: in planning, the analysis of data to predict market trends of products and production capacity requirements; in sourcing, the use of an agent-based procurement system; and in delivering products, the applications of business analytics in logistics management to bring the products to the markets more efficiently (Trkman et al. 2010).

The methodologies and technology to support integrated profit maximization planning are well established, and the required resources are not exorbitant. In fact, the use of mathematical optimization to support logistics and supply chain management practice can be found in such industries as the oil and chemical industry as early as the 1960s (Miller, 2002). Yet despite early pioneering work in certain industries, this remains an area of terrific opportunity for many firms because surprisingly few employ these techniques in their current strategic and tactical planning processes.

There are several reasons for the underutilization of optimization techniques in supply chain planning. Briefly, factors that have contributed to this relatively slow uptake include:

1. Until the last 15 to 20 years, employing these techniques required that a firm have employees with advanced operations research skills (- note this is no longer a requirement because of commercial software advances)
2. Many senior managers remain relatively unfamiliar and/or uncomfortable with the true benefits of this mathematical technique
3. Many senior managers believe they can make effective network planning decisions without investing resources in optimization tools (- this is related to factor 2 above).

MAIN FOCUS OF THE ARTICLE

A well-constructed and maintained decision support system (DSS) supported by advanced optimization analytics represents a critical tool to facilitate coordinated supply planning and execution. A supply chain planning DSS typically has numerous components (see Liberatore and Nydick, 1998 and 2003, and Liberatore and Miller, 2012) and will vary significantly by firm. For global manufacturing and distribution planning, the inclusion of mathematical optimization models within a DSS structure can represent the difference between a DSS that provides information and a DSS that truly facilitates integrated planning and execution.

Specifically, advanced analytics for global manufacturing and distribution that utilize optimization models which consider all of a firm's manufacturing facilities, distribution locations, transportation routes and modes, and customer demands can facilitate the development, implementation, and maintenance of globally coordinated plans and schedules. A cost minimization methodology represents the most common optimization modeling approach for integrated manufacturing and distribution planning. Particularly in single country domestic applications or in environments where tax rates in local regions do not represent major decision factors, a cost minimization methodology can help formulate an effective integrated plan. However, in planning scenarios where there exist differing local country tax structures, tax rates and intra-company transfer pricing options, cost minimization methodologies generally cannot identify profit-maximizing global production and distribution plans. Instead, profit maximization models that explicitly evaluate decisions such as where to incur tax liabilities and how to set intra-company prices are required to develop the optimal, integrated global manufacturing and distribution plan. An example may help to clarify this point.

Consider a firm that has a global three echelon supply chain consisting of:

1. An intermediate (i.e., work-in-process, WIP) plant located in country A,
2. A finishing plant located in country B, and
3. Finished goods warehouses located in 20 markets (countries) where it sells its finished goods produced by country B.

This global firm will have to establish the price at which country A will sell its WIP product to country B, and also the price at which country B sells its finished goods products to the 20 markets that sell its products to the external customers in their respective local countries. The cumulative net profits after taxes and exchange rate impacts of all these local country profits yields the overall global net profit of the firm. A global profit maximization methodology facilitates formulating an optimization model which will determine for the firm what prices should be charged by countries A and B to their internal customers (i.e., to country B and to the 20 markets, respectively) to maximize overall global firm profits. In developing its solution, a profit maximization methodology can directly evaluate the tax impact in each country, as well as the impact of global exchange rates. A cost minimization methodology, however, cannot identify as precise nor as optimal a solution because this methodology does not allow the model to determine intra-firm (i.e., inter-country) prices endogenously within the model. The profit maximization methodology, however, does allow the internal prices charged by the firm's affiliates (i.e., different countries) to each other to be determined endogenously. Therefore, taxes on local country profits, as well as exchange rate impacts, are considered in determining a global profit maximizing solution. This contrasts with solutions identified as optimal by a cost minimization methodology which may not be optimal when the true tax implications of a plan are considered. See de Matta and Miller (2015) for an extensive discussion of the benefits of the strategic profit maximization modeling approach. Additionally, illustrations of tactical level decision models

which account for taxes on local country profits and exchange rate uncertainties can be found in Kouvelis (1999), Sceller-Wolf and Tayur (1999), Kazaz et al. (2005), Shunko and Garvirnneni (2007), Villegas and Ouenniche (2008), Hammami et al. (2009), Nickel et al. (2012), and Hammami and Frien (2013).

Hierarchical Supply Chain Planning

To provide additional perspective, we briefly review how our global profit maximization models fit into the overall supply chain planning and scheduling activities of a firm. To facilitate this perspective, we consider a well-known hierarchical production and distribution planning paradigm. Briefly, the hierarchical production planning process (see for example Hax and Meal 1975, Liberatore and Miller 1985, de Matta and Miller 1993, and Miller 2002) stratifies manufacturing and distribution planning and scheduling activities into three levels: strategic, tactical (which includes annual) and operational. As Figure 1 illustrates, the analytics we describe in this article support the strategic planning level, and can also easily be modified to support tactical and operational planning. Next we describe three global profit maximization models. The first model is used to provide guidance on constructing a supply chain. The second model generates an integrated, detailed global production and distribution plan at the production line, plant and distribution center level. The third model facilitates scenario planning exercises to determine the optimal balance between inventory and manufacturing capacity investment on a supply chain network.

Formation of a New Supply Chain

The process of establishing a new manufacturing and distribution network or significantly modifying an existing supply chain represents a major challenge. The global dimensions of 21st century business where sourcing, manufacturing and

Figure 1. The hierarchical production and distribution planning framework

marketing options often exist worldwide compound the complexity of this problem. Consider the perspective of a firm that wishes to establish a new manufacturing and distribution network to source, make and deliver a set of products to an international marketplace. To weigh its options, the firm first evaluates a set of potential supply chain alternatives from a very high level, strategic vantage point. In the supply chain selection process, the firm will consider all traditional supply chain operations factors such as sourcing, manufacturing and distribution costs and capacities, inventory investment requirements, and all freight, duty and tax costs. Additionally, however, the firm wants to incorporate the potential impact of exchange rates and transfer prices between different entities and countries on this network. By evaluating all pertinent operational costs and capacities, as well as exchange rate and transfer pricing considerations, the firm can establish a “profit maximizing” rather than a “cost minimizing” global manufacturing and distribution network.

SOLUTIONS AND RECOMMENDATIONS

A Strategic Manufacturing and Distribution Model

A manufacturing and distribution network (MDN) model provides guidance on constructing a supply chain from a wide assortment of sourcing, manufacturing, and country alternatives. The model allows a firm to develop a set of major production activities (echelons) that will collectively comprise a complete supply chain from original sourcing locations to final market demand points. The firm can propose as many alternative production activities as desired. Once the firm identifies all potential production activities, the mathematical model generates the optimal supply chain to satisfy the market demand forecast and maximize the firm’s profits (i.e., the model creates a comprehensive sourcing, manufacturing and delivery network). Plans generated by the

model include a description of how the selected production activities collectively link together to form this supply chain, as well as the projected output levels of, and flows between all links on the network. The model also considers the fixed cost of providing support services, for example, any access roads and loading or unloading capabilities that a firm may have to develop. Additionally, the model projects the optimal transfer prices between the firm's affiliates in individual countries as they ship the intermediate products and finished goods across the supply chain to the ultimate market destinations. Through transfer prices, the firm can allocate global profits to these affiliates in producing countries. The model's profit maximization methodology incorporates the impact of exchange rates on the global profit of the firm as calculated at its home office (i.e., country of registry). Alternatively the MDN model can also support analyses of the impact of major revisions to an existing supply chain.

The purpose of the MDN model is to provide preliminary high level planning recommendations. Thus, reflecting this high level strategic planning role, it does not explicitly model individual production lines at potential plants. Instead, the MDN model treats manufacturing capabilities as production activities that have a total output capacity, as well as fixed and variable costs associated with this capacity. These production activities can be pieced together to form a complete supply chain. Figure 1 illustrates this model's strategic role and how it fits into the overall manufacturing and distribution planning framework.

A Strategic and Tactical Planning Model

Once a firm determines the exact construction of its supply chain (using the MDN model), the firm would need to utilize more detailed planning models to support additional strategic and tactical planning activities. The strategic and tactical planning (STP) model described in Miller and De Matta (2008 & 2009) explicitly models production

lines (both their individual costs and capacities), as well as inventory levels by product family and location. The STP model generates an integrated global production and distribution plan at the production line, plant and distribution center level. Thus, a firm can employ the STP model in its more detailed strategic and tactical planning exercises. In contrast, the role of the MDN model precedes the role of the STP model. To summarize, the MDN model assists in the process of developing new or significantly revised supply chain networks, and then other models that capture the network's operations in more detail takeover to assist the more mature strategic and tactical planning processes.

How Does the Global Profit Maximization Model Work?

The STP profit maximization model evaluates the trade-offs between factors such as production costs and capacities, distribution costs, taxes, local country profits and exchange rates. These evaluations and trade-offs facilitate the development of an integrated global production and distribution plan that maximizes global profits. Figure 2 illustrates this process for a network consisting of a single or multiple echelons of plants, a single echelon of distribution centers (DCs), and external customers. In this example, a global firm owns plants in a number of countries. It also owns DCs in a number of countries, and it has external customers in each local country where it sells its products. Note that the firm may not have plants and/or DCs in every country where it generates sales (i.e., the firm may export directly from one country to external customers in another country).

Enhanced Contingency Planning: The Manufacturing Capacity – Inventory Investment Trade-off Model

We now extend our base STP model to provide a firm with an additional strategic planning capabil-

ity; namely, the ability to evaluate the potential costs and benefits of “extra” investments in manufacturing capacity and/or inventory – beyond the normal level required to meet forecast demand fulfillment goals. An important dimension of contingency planning for a firm is deciding how much, if any, reserve manufacturing capacity and/or reserve inventory to maintain on its network. For example, in its strategic planning process, assume a firm has a “most likely scenario” forecast of demand on its network for the next five years. By “most likely” let’s say a forecast to which the firm assigns a 70% to 80% probability of materializing. Assume also that this firm estimates there is a 10% to 20% probability that actual demand over the next 5 years will exceed its “most likely” forecast by 50% (i.e., this is the firm’s “high side scenario” forecast). From a contingency planning perspective, this firm must decide how prepared it wishes to be to meet the “high side” forecast, which it estimates has at best a 20% chance of occurring.

The manufacturing capacity–inventory investment (MCII) model allows the firm to determine the optimal facility location, manufacturing capacity, and inventory strategies that maximize profits while providing sufficient capacity to meet this high side forecast – should the firm decide to plan for this scenario. Importantly, the model also calculates the incremental costs to the firm of building this reserve manufacturing capacity and/or extra inventory. Thus, the MCII model allows the firm to analyze the impact on profits and costs of alternative manufacturing and inventory strategies that will provide the firm with different levels of readiness to meet alternative potential future demand scenarios.

To facilitate this contingency planning, we introduce the concept of “safety margin”. We define safety margin as the sum of:

1. Total unused manufacturing capacity (in units), and
2. Total reserve inventory (in units) above the normal level of total safety stock required to assure a defined fill rate (i.e., customer service level).

Using the MCII model, a firm’s planners can conduct contingency planning exercises where they evaluate the impact of different levels and mixes of planned safety margins on the firm’s costs, profits and network design.

“Total unused manufacturing capacity” is simply the difference between the total manufacturing capacity available on a network and the total manufacturing capacity actually used. This unused capacity represents “reserve capacity” that a firm could utilize should actual demand exceed forecasts in the future. Thus, this reserve capacity offers the firm a safety margin to protect against future high side demand scenarios. However, this reserve capacity comes with a cost, and exposes the firm to future risks. Specifically, if the firm invests in sufficient plant and equipment to meet a future high side forecast, and if that forecast does not materialize, the firm’s future profits will be depressed by the ongoing higher than necessary annual fixed costs associated with this extra unused capacity.

“Total reserve inventory” is the difference between the total inventory and the planned total safety stock inventory on a firm’s network. In the MCII model solution, this difference can range from zero to the defined upper bound on total inventory on the network. If this difference has a value of 0, this denotes that a firm will not plan to carry reserve inventory, beyond safety stock requirements, on its network. A positive differential, however, indicates that a firm will maintain reserve inventory levels, above normal safety stock requirements, in preparation for potential future demand levels that may exceed forecasts (e.g., exceed the “most likely” scenario forecast).

To summarize, in designing their manufacturing and distribution networks, firms must proactively plan for a wide range of contingencies including the possibilities that future demand may significantly exceed forecasts, and that unexpected facility disruptions and outages may occur. Two major strategies that can protect a firm against these contingencies are to build reserve manufacturing capacity and/or to build reserve inventory. Both

of these strategies require substantial incremental investments which may or may not be prudent. The MCII model provides a firm with insightful, quantitative decision support to evaluate these two strategies across a broad spectrum of real world scenarios.

Firm Organization and Accounting

In these models, the global firm operates in many countries. It has a “home” country of registry (e.g., the United States) and “local affiliates” in all other countries where it has a presence. Presence may take the form of a number of different entities (e.g., a plant; a DC; a sales office and sales force; or an autonomous operating unit with manufacturing, distribution, sales, finance and all other attributes of a stand-alone company).

Plants of local affiliates/countries (and plants of the home country) ship finished products to distribution centers of local affiliates around the world. Distribution centers receive finished goods from plants and then subsequently ship products to the firm’s external customers. This flow from the DC to the external customer represents the actual sale by the firm to its paying customers.

As Figure 2 illustrates, the price or value of a unit of product increases as it moves through the network. A plant in a local country ships (sells) a product to another local affiliate (country) at an agreed upon price. This price, at the minimum, includes the costs of production and distribution, as well as a markup on the production and distribution costs of the producing plant (country). This price, which also typically includes additional cost components such as administrative overhead, represents the transfer or intra-company price that a plant charges the local affiliate to which it delivers the product.

After it acquires the product at an intra-company transfer price, a local affiliate then sells this product to an external customer at the local selling price. The difference between an affiliate’s acquisition price and its selling price consists of the distribution, sales, and other costs of the lo-

cal affiliate, as well as a markup or profit margin that the local affiliate adds to its acquisition and delivery costs.

In summary, the global profit maximization model illustrated in Figure 2 evaluates and accounts for the incremental cost or value added to a product from its cost as finished goods inventory at a plant to its selling price to the firm’s external customer. In the model, the combination of all costs accounted for after production through delivery to the external customer, (i.e., all costs added to the base production cost of a unit of finished goods inventory), plus the markups on costs recommended by the model, increase the product cost of a unit of finished goods inventory at a plant to its ultimate selling price to the local external customer. The selling price to the external customer is an exogenous, pre-determined input to the model.

There are two markups on cost that create profit margins and profits. These markups occur at the point of shipment (sale) from the producing country to the receiving local affiliate, and at the point of shipment (sale) from the local affiliate to the external customer. The model recognizes and evaluates the local taxes paid on the profits recorded by the plant (country) selling to another local affiliate, and on the profits generated by the local affiliate selling to the external customer. The model utilizes the appropriate exchange rates between local affiliates and the home country of the firm to project the total global profit of the firm. Note also that this modeling methodology can explicitly account for cost factors such as freight duties, insurance on freight, and other customs charges.

Global Operations Plan Developed By The Models

The MDN and STP models generate an integrated global operations plan that maximizes the firm’s global after tax profits subject to satisfying inventory, production capacity and customer demand constraints. The models develop profit-maximiz-

Figure 2. Basic network representation of our global profit maximization models

ing solutions that take into account manufacturing costs, distribution costs including customs and duties, taxes and exchange rate impacts. The MCII model facilitates additional scenario planning to evaluate alternative integrated inventory and manufacturing investment strategies. The plans of these models maximize the after tax profits of plants plus the after tax profits of markets which are based on the product landed costs. The MDN output is a supply chain network formed from a wide assortment of sourcing, manufacturing, and country alternatives. The STP output includes a production plan for each plant by production line. The MCII output develops an additional contingency plan to address higher than forecast demand levels and/or unexpected major supply disruptions. Additionally, all three models create a global shipping and sourcing plan that indicates plant to market to customer assignments. Finally, model solutions develop recommended intra-

company transfer prices (i.e., markups) between plants and markets, and between markets and customers taking into consideration local tax rates and foreign exchange currency impacts.

We should note that a multinational firm often has internal policies regarding the range of markup percentages it will allow on transactions between its plants and local markets around the world. In many cases, local country regulations also heavily influence these corporate policies. The methodology described herein can easily account for these types of constraints. For more details, and for the actual model formulations and solution procedures, interested readers are referred to Miller and de Matta (2008) and (2009), de Matta and Miller (2015), and de Matta (2016). (See also Goetchalckx et al. 2002 for similar models.) Additionally, for descriptions of implementations of strategic and tactical network optimization models employing both profit maximization and

cost minimization methodologies, the reader is referred to Arntzen et. al. (1995), Gupta et. al. (2002), and Miller (2009).

Notes On Model Data And Other Requirements

The data requirements for the models presented in this chapter will primarily reside within a firm. Typical data elements needed would include transportation costs between all origins and destinations, all pertinent production costs and capacities, and all distribution center costs and capacities. In addition to these types of internal firm data elements, external data requirements would include all pertinent country taxes and duties, as well as exchange rate information. The reader interested in more detailed descriptions of data requirements for these types of models is referred to Miller and De Matta (2008) and Miller (2002).

The models described in this chapter can be run on standard desktop and laptop pcs. From a software perspective, to solve the more complex global profit maximization models such as formulated in Miller and De Matta (2008) and De Matta and Miller (2009), it is necessary to employ specialized mathematical programming techniques such as the generalized Benders decomposition approach (Benders, 1962). For example De Matta and Miller utilized a canned optimization package (CPLEX 8.0 Users Manual, 2002) and a customized computer algorithm in C++ to build and solve profit maximization formulations. It is important to note, however, that there also exist user friendly commercial optimization packages which can easily solve a variety of large scale profit maximization problems.

FUTURE RESEARCH DIRECTIONS

The use of profit maximization optimization models to support business analytics remains limited. The limited use of this methodology by private industry stems primarily from lack of acceptance

rather than from any algorithmic limitations. Algorithms and heuristics to solve large scale linear and non-linear profit maximization formulations abound. What is missing is the general acceptance by supply chain executives that profit maximizing network optimization models represent an indispensable planning decision support tool for *strategic and tactical* supply chain planning. Many executives continue to think of these models as exotic, resource consuming luxuries for which simpler, easier to understand methodologies (e.g., spreadsheet based analyses) represent adequate, less mysterious substitutes. In recent years, however, the use and acceptance of optimization based decision support methodologies have made significant inroads in *operational* activities such as transportation and production scheduling. In the future, we anticipate this expanded utilization of optimization based *operational* DSS tools to help fuel an increased use of optimization models in *strategic and tactical* network planning also. Additionally, Sherman (2013) has recently suggested that global optimization models will also gain popularity in the future as a supply chain risk assessment decision support tool. Thus, we expect a moderate, but steady adoption of optimization based network planning models, including profit maximization models, to occur in private industry in the coming years.

CONCLUSION

In conclusion, there exist numerous advanced analytics applications for hierarchical production planning that can utilize these global profit maximization models. We will briefly highlight several applications which address the strategic planning horizon, and also discuss how advanced business analytics can be employed for tactical planning purposes.

- The MDN model provides an integrated production and distribution framework for developing global supply chain plans

for a 2 year or longer planning horizon. Typically, planners would run the MDN model once a year to review the sourcing, capacity and delivery requirements of a firm. In this strategic application, the model can assist the firm to form or enhance a supply chain to make and deliver a new set of products to an international marketplace. This model can also support strategic decisions such as potential changes in production strategies using existing plants. For example, one can evaluate decisions regarding potential shifts in production of major products between plants.

- The STP model provides an integrated production and distribution framework for developing global supply chain plans for a 12 to 24 month planning horizon. Typically, planners would run this model once a quarter or every six months to update production plans for each plant and sourcing plans that recommend plant-to-warehouse to country (customer) assignments. In this tactical application, the model assists in determining the global plan that maximizes profit using existing supply chain infrastructure.
- Both the MDN and STP models provide excellent sensitivity analysis capabilities for strategic and tactical planning. Specifically, planners can employ these models to evaluate the impact of potential changes in exchange rates and local country taxes on medium and long-term plans. Examples include the following. At the tactical level, once an initial global plan is developed one can run the model with alternative exchange rate assumptions to determine how robust the recommended production plan is. Do production and sourcing decisions remain relatively constant over a wide range of exchange rates, or do plans vary significantly with relatively minor changes

in exchange relationships? At the strategic level, one can evaluate the potential impact of exchange rates or changes in local tax policies on long-run plant and distribution center location decisions.

- With production and distribution activities assigned to geographically dispersed facilities to form a supply chain, inventory and capacity contingency plans to reduce the risk associated with higher than forecast demands or unexpected disruptions to the supply chain can be developed using the MCII model (Handfield, 2007).
- One can also develop plans to address factors such as the impact of duty drawback opportunities and “local content” type production and distribution regulations.

These few examples provide a brief glimpse of the many potential applications that these planning models can facilitate.

In this chapter, we have stressed that global profit maximization models can address both the strategic and tactical planning levels. We believe that models for advanced business analytics such as described herein can play an important role in guiding plans for the overall operations of large-scale manufacturing and distribution networks at these longer term horizons. There are relatively few “reported” implementations of long run, strategic or tactical global profit maximization models for large-scale networks. Thus, we believe that the implementation of global profit maximization models represents a potentially significant unrealized opportunity worthy of serious consideration by many firms. This methodology remains heavily underutilized in private industry. Further, as previously noted, the investment and resources required to develop this capability within a firm are relatively modest, and the potential return on investment is extremely high.

KEY TERMS AND DEFINITIONS

Decision Support Systems: Planning and scheduling tools that utilize an organization's data warehouses and other data flows to generate inputs to management decision-making.

Hierarchical Planning Time Horizons: Consists of the strategic (long run), tactical (medium term) and operational (short run) planning and scheduling horizons.

Hierarchical Supply Chain Planning: Represents an approach and a philosophy towards the organization, planning and scheduling of supply

chain activities which facilitates alignment between all short run, medium term and long run activities.

Operational Planning Horizon: Encompasses all planning and scheduling activities related to an organization's plans and schedules from the next one to eighteen months, with a primary focus on the nearer term.

Strategic Planning Horizon: Encompasses all planning activities related to an organization's plans for two years to as far into the future as the organization develops formal plans.

Supply Chain Optimization Models: Planning and scheduling models based on the mathematical techniques of linear, mixed integer and non-linear programming.

Tactical Planning Horizon: Encompasses all planning activities related to an organization's plans for the next 12 to 24 months, and includes the annual budgeting process.

Transfer Pricing: The price charged by one affiliate (i.e., subsidiary) of a multi-national firm to a second affiliate of the firm for goods and/or services produced and delivered to the second affiliate by the first affiliate.

Radio Frequency Identification Systems Within a Lean Supply Chain in a Global Environment

INTRODUCTION

Supply Chain Management (SCM)

The ultimate goal of supply chain management (SCM) is to effectively and efficiently manage the movement of material or products through the supply chain cycle (Mateen & More, 2013; Park & Min, 2013). Such a lofty goal is accomplished only through the creation of strong partnerships with suppliers and customers, reduction of waste, and maintenance of product visibility to insure both quantity and quality meet predetermined requirements (Boerner, 2010a, 2010b). As SCM has matured as a discipline, so has the implementation of some tools to assist in achieving these goals, while still maintaining a green or sustainable presence (Berthon, Critenden, Desautels, & Pitt, 2010; Beamon, 1999). One such tool is the application of a lean production mode, which can assist in the achievement of waste reduction goals throughout the supply chain, especially when strategic partners apply the same principles. Another valuable tool is the utilization of large corporate IT-infrastructures and analytical data warehouses (Ha, Park, Lee, & Park, 2013; Mehrjerdi, 2009; Smith, 2015). As an added enhancement to a lean

supply chain, the use of real time data from these IT-infrastructures gives firms better details of current information and product movement. The use of real-time data sharing from both intra-firm and external partners is ideal for more accurate forecasting and reliable model development.

A supply chain is the sequence of activities to get materials or products to end-users. A firm's supply chain includes all steps from raw material to final product, as well as assurance of customer satisfaction (Smith, 2010, 2015; Smith & Minutolo, 2014). In the past, most firms have been concerned only with the work completed within their shop. Unfortunately, this has led to a rather disjointed supply chain characterized by higher inventory levels, poor forecasting ability, and limited visibility or products as a whole. The use of supply chain management as a means to remain competitive in a global economy is an essential component for financial success. In today's global business environment, effective SCM is crucial to enhancing business performance. It is a collaborative effort on the part of management to position and run the supply chain in the most efficient and effective ways possible. This effort covers activities from product development, sourcing, production, and logistics, as well as the

DOI: 10.4018/978-1-5225-2255-3.ch479

information systems needed to coordinate these activities.

Creating strong partnership with a select supplier base can allow for better communication and product knowledge (Browning & Heath, 2009; Cavaleri, 2008). Aligning firms with likeminded suppliers is a key activity of SCM. With the use of a select supply base, firms are better able to share pertinent data across supply chain members. Above all, this leads to better quality and reduced waste.

Understanding Lean Elements

Lean is a paradigm advocated as the foundation for a competitive SCM. Lean methodologies are well known in the corporate world, but sometimes hard to define due to the many aspects associated with successful implementation. A simple definition could be doing more with less; however, that definition underestimates the transformative power within the supply chain. As provided in Cabral and Cruz-Machado (2012), the term 'lean' implies a series of activities or solutions to eliminate waste, reduce non-value added (NVA) operations, and improve the value added (VA) process. Lean production is often connected with 'zero inventory' and just-in-time (JIT) approaches.

Lean principles were initially made popular by the Japanese manufacturing industry and most notably the Toyota Production System (TPS). The goal of lean is to simply balance the flow of materials with customer needs while maintaining optimal cost, quality, and customer service. A number of common elements define the scope of lean, helping management create a competitive firm. The implementation of lean practices does not guarantee success, but includes a primary goal of waste reduction through removal of NVA processes, reduction of excess inventory, limitation of material movement, minimization of production steps, management of scrap, and reduction of reject and rework (Carvalho, Cruz-Machado, & Tavares, 2012; Chan & Kumar, 2009; Grewal, 2008; Jain, Benyoucef, & Deshmukh, 2008;). Through worker-management relationships, a

firm can engage in a continual assessment of processes, methods, and materials for the value added to saleable products.

Purpose of Present Study

This chapter will look at the impact of using Radio Frequency Identification (RFID) systems within a lean supply chain, reviewing current research papers using a qualitative business case study approach (Baxter & Jack, 2008). Managers need to be able to justify an augmentation of lean practice and real time data with the use of RFID to improve SCMs ability to improve the goals of reducing waste and improving product visibility throughout the supply chain.

BACKGROUND

Lean Elements in Managing Supply Chains

Managing supply chain relationships by working with suppliers to meet the goal of waste reduction are essential functions for successful businesses. Firms often keep safety stock to adjust for inconsistent timing and quality of a supplier. Likewise, operations may have to manage work-in-process inventories for their own processing issues. Holding stocks of finished goods for longer periods of time before shipping to customers to avoid stock outs and maintain customer service levels adds to total costs. Unfortunately, all of these added inventories add little to no value to the company, while costing a considerable amount (Hu, Wang, Fetch, & Bidanda, 2008). Working with suppliers and customers can reduce shipment sizes while reducing inventory. Likewise, having the right inventory positioned nearer to the right customers assists in the firm's outbound shipments costs.

Lean layouts keep with the concepts of waste reduction (Drejer & Riis, 2000), minimizing the movement of workers, customers, and materials to create a more meaningful production and

distribution flow. The goal is to place people and products logically such that parts and people are positioned in the places they are needed. Visibility is central to this; line-of-sight should not be blocked. Additionally, the addition of quality checks at processing centers can assist in the reduction of rework and rejects.

Inventory and setup time reduction pull from production and distribution elements. If there are supplier or customer issues, larger inventories are likely. If there are setup time issues, layout issues are probably at hand. In this case, the need to reduce non-value added activities is part of issue identification. Properly aligning supplier and customer expectations will assist in the reduction of inventories, while updating layouts will allow for the needed flow of material to ramp up startup times.

A considerable amount of communication networking is required to properly address small-batch scheduling (Bhat, 2008; Baxter & Hirschhauser, 2004; Biswas & Sarker, 2008). The idea focuses on the ordering and production of products based on smaller, more frequent shipments. Understanding and attempting to mitigate all the SCM issues that arise is critical during this time. A main goal is minimal inventory and smaller lot sizes, at zero levels of inventories. Moving products effectively is extremely important and having the right product at the right time is even more crucial. Therefore, the need for a dedicated supplier base and a lean layout will prove effective in establishing supplier collaboration and integration policies and practices. The ultimate financial payoff of such a system is reduced cost of managing bloated inventories.

The previous components and their integration can be summed up with the goal of continuous improvement. In the case of lean layout, there is always room to improve a processing center's position or material location (Dasci, & Laporte, 2005). Reducing inventory and setup time have their own issues and any problems must be quickly resolved as suppliers and workers must continuously adjust to the faster pace of business. Once

proper communication channels are established and mutual trust and benefits are created, firms should seek to implement smaller inventories or improve the levels of current inventories. Likewise, always pushing for improved quality at lower costs requires continuous improvement strategies. Whether it is a bad stock from a supplier or product that does not meet requirements, continually monitoring and improving quality is an essential element in a lean production environment. This situation becomes even more complex in an outsourcing/offshoring environment (Wee, Peng, & Wee, 2010; Whitten, 2004).

Offshore outsourcing is the practice of contracting to outside vendors in another country, in which the client company has no direct ownership. The low-cost approach, expansion in number and increased capability of offshore outsourcing vendors in India, China, the Philippines and others, presents the opportunity to assess the hierarchical organization of functions such as software development, call centers and accounting. Since the late 1990s, offshoring as a major type of outsourcing has included ever more sophisticated finance and accounting functions, beyond that of simple data input and transactions. Offshore finance and accounting outsourcing (FAO) is becoming an increasingly attractive option for many companies, offering a means of gaining access to scarce skills, cutting costs, and achieving competitiveness (Hall & Liedtka, 2005; Nicholson & Aman, 2012).

Despite the rapid growth of the FAO industry, particularly in India, the industry has faced challenges in staff attrition. Attrition contributes to high annual turnover rates, shortages of qualified entry-level manpower, shortages of capable middle-managers, and rising wage costs. Attrition is costly to organizations, especially when those leaving their jobs are highly talented. Attrition is costly to both the provider, which must hire and train replacement employees; and also can be problematic for clients, due to the potential disruption to service when an outsourced employee leaves. Excessive attrition increases the risk of diluting service quality, affects business development ef-

forts, and impacts client relationships through the lean supply chain. Although issues of attrition are prevalent in the FAO industry, only a few studies have sought to examine how institutions influence the way firms control attrition.

The last major element of the lean production system is perhaps the most critical. Worker empowerment/commitment is required to achieve most of the previously discussed elements, as evident from the previous discussion of the FAO industry. Managers must show a strong support for a lean production system, giving their subordinates the needed resources, skills training, time, and tools required to identify process problems and bring the appropriate change to address the issues. Managers must create an environment in which the employee can bring up issues. Successful implementations of lean is difficult and many companies do fail by not being able to stay on track with the smaller faster shipments and keeping up with the continual improvements. Even after implementing a lean production system, a company can fail to engage in continuous improvement which can lead to waste and, ultimately, hinder the ability to continue in a lean production environment, with poor financial accountability (Kennedy & Widener, 2008).

Real-Time Data in SCM

SCM can take advantage of the IT-infrastructure to gather pertinent data on the firm, suppliers, products, and the market. Firms can employ many systems, including Enterprise Resource Planning (ERP) systems, large data warehouses, Business Intelligence (BI), and Customer Relation Management (CRM) systems (Smith & Offodile, 2007). Using data gathered from these systems, firms can develop a supply chain management system that offers a great advantage over the competition. Using large datasets of both historical and present data, SCM can improve forecasts and understanding of demand of current products. Likewise, using real-time point-of-sale data, SCM can better understand current customer demands. Predicting future development needs, SCM can better meet the demands of the customer.

Real-time data can be shared between the firm and strategic partners to advance SCM operations. When both supplier and customers have a better visibility of product and demand they can more effectively work together to meet the changing demand of the supply chain. Real-time data sharing can help to reduce the need for safety stock and work-in-progress inventories. Real-time data improves the tracking of materials and products both in the firms and throughout processing centers or external supply chain activities. Real-time data gives SCM a good level of visibility and improves the data used in forecasting, while providing a level of automation.

Barcode vs. Radio Frequency Identification Systems (RFID)

The current standard in inventory management is the barcode, the simplest tool in the automatic identification and data capture arsenal. Scanning a barcode provides the item's identification in the least expensive yet relatively secure manner. The scanner connects to backend databases of the IT-infrastructure and locates the item identification characteristics, linking the scanner to any pertinent information on the item it scanned. Such scanning can be done by an employee or an automated system and helps SCM track many attributes of the item such as weight, dimension, stage, and movement history. Automatic identification technology is essential for any production setting, as knowing where the material is located and minimizing non-value activities are part of the lean manufacturing structure.

Barcodes, however, have some limitations. One of the most noteworthy is that they require line-of-sight. In order to scan a barcode, the item labeled must be situated so that the scanner can read it. This requirement results in a loss of time and labor of an individual or system. A scanner can scan only one barcode at a time, meaning many labeled items must be properly aligned and scanned. Similarly, barcodes can represent

only the data that was printed. A typical barcode is read only and the amount of data that can be stored is very limited, although recent innovations in technologies, such as three-dimensional barcodes, have expanded greatly the amount of information that can be stored and accessed cheaply.

Most barcodes use standardized symbology that is certified by an international standards body (GS1 System). This system provides for the universal global acceptance of many types of barcodes designed for a variety of shipping and identification applications. (Example barcode formats in common use today include EAN/UPC, GS1 DataBar, GS1-128, ITF-14, GS1 DataMatrix, GS1 QR Code, and Composite Component.) However, a labeled package can only be what it was first labeled as. This information can be linked to back-end databases, but each firm could have its own interpretation of the item and, therefore, it is harder to share among elements of the whole supply chain. Since there is no way to reprogram a barcode if a package is mislabeled then a new label must be generated and applied to the item. While these issues may seem minor, occurrences throughout the supply add up to significant waste. Even with these limitations, an IT infrastructure has been built around the barcode, making it costly for a firm to switch to a new system; however, there are motivations to push SCM to a newer form of inventory management system, namely RFID.

As far back as June 2003, for example, Wal-Mart mandated that its top 100 suppliers place RFID tags on pallets shipped to their locations in the Dallas, Texas region (Delen, Hardgrave, & Sharda, 2007). This was motivation not only for suppliers of Wal-Mart to start looking into the use of RFID, but SCM as a whole. Shortly afterward, the Department of Defense, Target, and Alberston's followed with mandates of their own. With a surge of use by these dominant companies, RFID technology is starting to be explored as the replacement to the barcode.

RFID Technology

The basic system of RFID is composed of a tag, readers, and middleware (Kwok & Wu, 2009). The tag is placed on a pallet, container, or item and when passed by the readers are read. The tag itself consists of a chip and antenna. The two higher level types of RFID tags are passive and active tags. Passive tags have no power supply, require no maintenance, and can potentially have an indefinite operational life. These can be made small enough to be an adhesive label of its own but derives its power to operate from the electromagnetic field generated by the reader as it communicates with the reader. Active tags consists of a battery that powers the microchip and broadcasts the signal to an RFID reader. Table 1 illustrates basic data that RFID systems can typical capture about inventoried items. The reader is used to send a signal to the RFID tag activating it and allowing the transfer of data to the reader.

The use of RFID-related systems has a number of important and significant advantages over barcodes. RFID does not require line-of-sight. Tags may be read at varying distances. Further, RFID tags can be read in bulk. While this simplifies the task of reading larger areas or containers into inventory, it is important to note data accuracy issues exist when reading larger numbers of items.

Another advantage is the read-write capability of the tag, which contains information and passes it along to the distribution centers and retailer. A key to this is the use of Electronic Product Code (EPC). This is a universal identifier that gives a unique identity to the item to which the tag is affixed. The identity is made to be unique so that each object is identifiable within all of the objects. EPC creates uniqueness that is made to last over the area of the object. This, along with the ability of the RFID to capture, store and send data to reader, gives SCM more details of how and item may move among the warehouse or data center as well as throughout the SC. Table 1 demonstrates the use of RFID to monitor the

Table 1. Typical RFID-related systems data capture

movement of an item as it moves from the truck to throughout the data center on its way to end of life. Insight such as this shows the real value RFID can add to SCM. These data can easily be shared with partners to help them better understand the movement of the product. The added benefits of this product visibility are a key reason why SCM is starting to adopt the idea of RFID over the conventional barcode.

MAIN FOCUS OF THE ARTICLE: BUSINESS CASE FOR RFID IN SCM TO IMPROVE LEAN OBJECTIVES

RFID Advantages

RFID presents several advantages over use of the barcode, tracking data about the item(s) to which it is attached and creating improved real-time product visibility. This is especially useful to lean firms, which—despite adherence to the principle of waste reduction and work to identify waste—do not have an easy way to visualize all the movement taking place in a given supply chain. Real-time data tracking via RFID makes this possible.

As RFID-tagged items move and tags are read, the RFID tag keeps data which can then be gathered and analyzed. With this technology, firms can find bottlenecks in the supply chain, develop real-time

solutions, and manage the work (Mehrjerdi, 2009). A virtual and tractable supply chain offers great advantage, as models can be used to track product and personnel issues and improve layout to create a better supply chain flow. The real-time data can be integrated into the firm's ERP and point of sales (POS) systems. A case study of this was completed using the textile industry:

RFID Integrated With ERP Systems

To apply RFID technology within a supply chain, a series of RFID gateways are installed in a series of stages of the textile chain. The RFID gateway acts as a check-in and check-out system, and synchronizes the in/out status to ERP in real time. RFID integrated with POS systems. For international retails, POS systems are commonly used to calculate shipping amounts and stock balance. An RFID gateway installed in a retail shop helps the shopkeeper check-in new stocks. A mobile RFID handheld device can be used for stock-taking (Kwok & Wu 2009). Having this type of 360-degree view of product movement from raw material to item at end of life creates a new model for managing inventory. Companies can greatly improve their current processes by reducing the number of human touch points of the products in their systems (Delen et al., 2007). As Chongwatpol and Sharda (2013) found, out of the

major activities that create waste, inventory level, overproduction, waiting time, processing time, cycle time, and backlog orders, RFID-embedded technology outperforms barcodes in reducing levels in all but overproduction.

A model can be implemented so that rather than having an employee physically inventory an item a reader at the loading dock can read a pallet. Dependent on the material, certain automated processes can be triggered. Likewise, when an RFID streams data and items at a retail store start to get low a shipment can be processed at the warehouse for a shipment. Streaming real-time can help firms better understand the movement of material in the supply chain and better prepare their inventory levels for market demands. As a fundamental part of lean is waste reduction, RFID certainly has a value-adding effect when it comes to finding new avenues to cut waste out of the supply chain.

Probably one of the most successful uses of an RFID is between strategic partners. The barcode did not have the ability to pass data along to the next stage in the SC. With RFID there is a new way for data to be interchanged between all members of the SC. With the standardization of EPC all companies can use the data as items are read. This can provide all members of the supply chain with invaluable information for forecasting of market demand and modeling of the current supply chain to best determine where more improvements can be made.

CONCLUSION

Overall, SCM has many tools, especially lean techniques, to use for improving the effectiveness of the supply chain. The goals are always to cut cost and find improvement to add value to the firm. A successful implementation of lean practice is a good step to continually improving the supply chain processes and workflow. The use of real-time data analysis can provide insight into the workings of the firm and market especially

when this data is shared amongst strategic partners. Emerging technology of RFID system for the transfer of data in real-time from within the firm and at large in the supply chain give SCM new ways of exploring the workings of their supply chain while simultaneously assisting their strategic partners so that all may better forecast and meet the demand of the market.

FUTURE RESEARCH DIRECTIONS

There is little doubt that RFID technology provides many benefits to companies (e.g., improved inventory control, less cost and shrinkage, greater security and authentication), but initial investments in a comprehensive system is still costly. Management must always be aware of what level does the cost of the system outweigh the benefits. Based on previous studies already cited, a RFID system used to identify a pallet of products for a company can provide a savings for that level of goods, but on an individual item the cost of the RFID system could outweigh the benefits. Therefore, additional research needs to focus if the members of the supply chain are able and willing to share the cost of RFID will this increase the benefit to the each member of the supply chain and who would benefit more. Ultimately, it may be the non-technology factors (e.g., accounting on operational processes, inventory forecasting accuracy, actual demand, case size, available shelf and warehouse spaces), that aid management in balancing the costs/benefits in any RFID embedded system and its maintenance in the strategic decision to implement such systems.

ACKNOWLEDGMENT

The authors wish to thank most heartedly for the valuable contributions by the reviewers for their input into the final paper. Peer reviewing and editing are commonly tedious and thankless tasks.

KEY TERMS AND DEFINITIONS

Barcoding Technology: A long-term and very reliable type of AIDC technology, it is known for its very accurate and economical approaches to identity products and machine readable information from a variety of manufactured goods and services. Most barcodes use a type of standardized bars and spacing coding or symbology that is certified by an international standards body (GS1 System). This system provides for the universal global acceptance of many types of barcodes designed for a variety of shipping and identification applications. Example barcode formats that are in common use today include EAN/UPC, GS1 DataBar, GS1-128, ITF-14, GS1 DataMatrix, GS1 QR Code and Composite Components.

Electronic Product Code (EPC): EPC is a universal identifier that gives a unique identity to an item a RFID tag is affixed to. The identity is made to be unique so that each object is identifiable within all of the objects' field.

RFID-Embedded Technologies: RFID technologies are types of automatic data capture techniques that use a combination of active and passive senders and receivers to collect and store codified information for further uses. The implementation of such technologies should lead to improved managerial and/or supply chain performance. On the surface, there appears to be few drawbacks to implementing such technology into a production process, assuming it enhances performance and improves output of the product. The main issues surrounding the RFID applications are whether the initial costs and labor required to utilize this technology are worth it, and will result in a positive outcome of revenues.

Reflections of the 1Malaysia Supply Chain (1MSC)

INTRODUCTION

Malaysia aspires to achieve a developed, high income nation status by the year 2020 (National Economic Advisory Council, 2009). Gearing towards that direction, Malaysian Prime Minister introduced a New Economic Model (NEM) intended to liberalize the economy. Among the eight Strategic Reform Initiatives (SRI) proposed in NEM is the need to have better integration between products and between production centers, so that economy of scales can be created and ensuring sustainability of growth economically, environmentally and socially. Recognizing the importance of a collaborative and integrated supply chain to seamlessly produce an output that meets a market demand and that is socially conscious, Sheng (2010) introduced a new concept called 1Malaysia Supply Chain (1MSC) in 2010. It consists of three strategic directions: Focus, Simplify and Integrate – basically all that is needed to integrate to achieve higher productivity, economies of scale and be sustainable focused.

BACKGROUND

Manufacturing industry is the biggest contributor to Malaysia's economic growth. According to a report from Malaysia External Trade Development Corporation (MATRADE), the Electrical &

Electronics (E&E) industry is one of the leading industries, contributing 24.5 per cent to the manufacturing sector in the Malaysia's Gross Domestic Product (GDP). In 2014, Malaysia's exports of E&E products was valued at RM231.23 billion, with 49.2 per cent share of manufactured goods exports and 32.9 per cent share of Malaysia's total exports.

Although the manufacturing industry has flourished, there are several challenges that the industry faces such as rising operational cost, scalability and rapid technology advancements. In addition, there is fierce competition between rival supply chain networks in the industry (Lo & Power, 2010). Currently, manufacturing industries are resorting to outsourcing the non-value added activities to contract manufacturers or suppliers. Most manufacturing companies have adopted to integrate their supply chain in order to obtain visibility into the supplier's deliverables and to detect possible issues upfront. While with supply chain integration (SCI) the operational cost can be lowered to an extent, it still does not address the gap of limited number of capable suppliers in the market to support the growing industrial needs. Thus, collaborative relationship with suppliers is needed (Stock, Boyer & Harmon, 2010).

Lack of technological expertise in a region have also becomes a bottleneck that hinders manufacturer's speed to market an innovation. These challenges raise a pressing need to develop

an effective and efficient SCI in a supply chain network (Huang, Yen & Liu, 2014). A successful SCI depends on information, coordination, and organizational linkage (Lee, 2000). However, the empirical results of SCI in the literature have been inconsistent. There is little evidence that integration provide improvements in effectiveness and efficiency (Fawcett & Magnan, 2002; Bagchi, Chun Ha & Skjoett-Larsen, 2005; Fabbe-Costes & Jahre, 2007). This is due to lack of clear definition of SCI and variation of definitions and interpretation of the concept (Fabbe-Costes & Jahre, 2007; Van der Vaart & Van Donk, 2008). Thus, scholars need to develop a model encompassing factors of SCI to benefit both practitioners and scholars (Zhang, Gunasekaran & Wang, 2015). To address this issue, this chapter took the challenge and proposes nationwide SCI by adopting the 1Malaysia concept.

The 1Malaysia concept was introduced by Malaysia's Prime Minister in year 2010 which comprises of eight values as its key motivators. Culture of Excellence, Perseverance, Humility, Acceptance, Loyalty, Meritocracy, Education and Integrity are the motivators behind the implementation of this concept. It focuses on national unity and ethnic tolerance which aims to bring the multicultural and multiethnic population as one. During its design and introductory phase, the concept was unclear to many and was considered as an alienated topic. This concept has now been progressively acknowledged and Malaysian has been utilizing the facilities that 1Malaysia offers such as the 1Malaysia clinics and the Kedai Rakyat 1Malaysia (KR1M). The driving force behind the realization of this concept is the strong foundation of its supply chain which integrates different parties as one.

The 1Malaysia concept coupled with SCI forms the proposed nationwide SCI called the 1Malaysia Supply Chain (1MSC). The outcome of 1MSC is to achieve supply chain performance and social performance, in which SCI failed to reach consistent results (Cousins & Menguc, 2006; Chen, Mattioda & Daugherty, 2007; Sezen, 2008; Flynn,

Huo & Zhao, 2010). This chapter shall explore a similar integration which has been successfully implemented in Malaysia through the KR1M initiative (component of 1MSC).

This chapter is organized by first explaining the overview of SCI concept and its challenges that would be relevant to the 1MSC concept. Then, the chapter discusses elements in the conceptual view of 1MSC and its contributions. Last, this chapter provides recommendations, future research directions and conclusion.

SUPPLY CHAIN INTEGRATION (SCI)

As 1MSC concept is derived from SCI, it is important for reader to fully understand the concept of SCI. Nowadays, the concept of companies versus companies has been replaced with supply chain versus supply chain competitiveness strategy, however only a small number of companies have implemented a fully integrated supply chain (Georgise, Thoben, & Seifert, 2014). The 1MSC concept involves collaboration and coordination within a supply chain, adopting a similar integration concept with the SCI. SCI is a topic that often being discussed in the supply chain management (SCM) literature (Power, 2005; Guan & Rehme, 2012) and has been widely studied by researchers such as Danese & Romano (2011), Zhang et al. (2015) and Yunus & Tadisina (2016). Firms require integration of all product flow procedures in order for SCM to be effective and efficient (Huang et al., 2014); hence collaboration among the stakeholders plays a vital role in ensuring smooth activities for the firms. SCI is beneficial to firms as it provides operational flexibility to respond to dynamic global needs, actions of competitors and changes in customer demand. Collaborating with supplier for instance enables firms to order materials as needed and response to customer's needs and requirements.

As defined by Flynn, Huo, & Zhao (2010), SCI focuses on strategic collaboration and process integration by looking at the extent to which a

manufacturer deliberately works together with its supply chain partners in dealing with internal or external practices and procedures. Leuschner, Rogers & Charvet (2013) on the other hand defined SCI as the scope and strength of linkages in supply chain processes across firms. SCI has its own characteristics such as having the basic objective and goal in meeting customers' needs, systematic and well defined procedure, and quick and ongoing communications between stakeholders.

According to Awad & Nassar (2010a), the integration of technology, people, business and processes is critical for survival and competitiveness in the current era, and its importance goes not only within a firm but also across extended enterprises. Hence, a good relationship with stakeholders requires firms to adopt SCI as a strategic tool and sharing of information. Information sharing refers to the degree to which critical and copyrighted information is communicated to other supply chain partner (Mohr & Spekman, 1994). Flynn et al. (2010), Gimenez, (2006) & Van der Vaart & Van Donk (2008) concluded that information sharing is part of an integration measurement in almost all surveys conducted on SCI. Thus, it is important not to neglect this driver as its importance has been proven in previous studies. According to Yu, Yan and Edwin (2001), information sharing is important to reduce uncertainties and supply chain performance can be achieved by changing decentralized supply chain to centralized method. This view is seconded by Awad & Nassar (2010a) that the most significant form of SCI was information sharing. The ability to facilitate, coordinates, and integrates the flow of information across the supply chain helps supply chain members to establish partnerships for better performance.

Although SCI brings benefit to the firms, it possesses great amount of challenges as well. Integration requires alignment between all stakeholders in order to achieve improved performance and service. In order to do so, knowledge sharing is deemed important and the sharing could be done through setting up common system. Technical

capabilities have its own challenges, especially in term of relation between SCM system and internal business strategy.

According to Awad & Nassar (2010b), certain challenges related to SCI are due to differences in firm's strategy theory and concepts, different ways of satisfying the needs and wants of customers from competitors, handling of logistics arrangement differently, difficulty in maintaining standards due to differences in elements such as the size and culture and importance of determining supplier's capability. Thus, the development of 1MSC concept aims to addresses these challenges in its implementation.

1 MALAYSIA SUPPLY CHAIN (1MSC)

1MSC is a term coined by Sheng (2010) and Zailani (2011). However, it has not been extensively researched and relatively unknown to both local and global scholars. This is because 1MSC is viewed as political agenda and lack of public awareness. Leveraging the concept of SCI, this notion goes beyond solely focusing on economic goals to also include sustainable development that encompasses fulfilling social and environmental objectives. According to Zailani (2011), the 1MSC aims at achieving targeted economic growth while at the same time contributing towards equally disseminated value-added productions and services among all players in the supply chain.

The 1MSC's strategy is to "Simplify, Focus and Integrate" that is, the supply chain network collaborated (integrate) and moved towards meeting the needs of all its stakeholders and parallelly providing platform to support business to improve value chains (simplify), finding new market niches as well as improving sustainable practices (focus) (Zailani, 2011). To do so, the Small Medium Enterprises (SMEs) have to be integrated into the larger global supply chain (with larger firms) and not dependent on subsidies in order to succeed in the long-run. Malaysia focusing on productivity-led and private led-growth, growth through clusters

and encourage technologically capable firms and industries and simplification of government structure, regulatory framework and a much-reduced role of government in business are required to ensure the successful implementation of overall national economic strategy (Sheng, 2010).

According to Sheng (2010), 1MSC would assist in achieving the NEM's goal by:

1. Integrating silos and production chains to be able to compete globally.
2. Using international standard as a reference to connect unrelated and overlapping policies, agencies towards achieving national objectives.
3. Achieving cluster efficiencies.
4. Directing attention to corruption and rent-seeking that hinders efficiency.
5. Developing SMEs to be part of global supply chain.
6. Providing feedback mechanisms from private sector to make supply chains more efficient and/or responsive.
7. Educating and re-training system to ensure labor force meets market needs and benefits from greater value creation.

In order to achieve these objectives and making 1MSC a success, there rise needs to have a single governing body to oversee and facilitate the integration. This body would be accountable to develop policies, guidelines and setup mechanism to bring all relevant stakeholders of the supply chain together. The authors proposed that this governing body be termed as National Development Incubator (NDI) and be setup as a government entity. This is the main driver for 1MSC in Malaysia that differs from current SCI concept.

NATIONAL DEVELOPMENT INCUBATOR (NDI)

The unique indicator that differentiates 1MSC from the conventional SCI is the introduction of NDI. NDI is a governing body that oversees the integra-

tion of all key players. NDI should develop unique and tailored responsibility for each of the players in the 1MSC namely i) Supplier, ii) Manufacturer, iii) Distribution Channel and iv) KR1M. Each of said elements is important to NDI. The NDI is targeted to address the challenges in SCI's implementation.

Supplier Vendor Program

In current supply chain models, individual firm focuses in selecting their own suppliers. Due to individual search, it resulted in a limited number of suppliers for each firm and focuses on small circle of network. The essential concept for the 1MSC is to introduce the supplier vendor program where selection of qualified pool of suppliers is done upfront by the NDI in order to address supplier's issue. According to Li & Zabinsky (2011), selecting the correct supplier has turned into a vital issue for firms. Each of the suppliers has its own strength and must fulfill the standard that has been imposed; however it is important for a firm to determine which suppliers are best suited. If it is not carried out as carefully and systematically as needed, there is an increased risk that the chosen suppliers will fail to perform effectively.

The common supply chain process which begins with limited number of suppliers, market dominating assembler and distributor is no longer relevant in the 1MSC context. Typically, the multiple local suppliers provide support either in goods or services to the manufacturers namely the SMEs or Multi-National Corporations (MNCs), however adhering to certain requirements or restrictions would impose some challenge to them and that is the issue that 1MSC expected to solve.

Ekici (2013) has outlined the four main criteria for suppliers' selection. Similarly, NDI have been adopting this criterion in the context of 1MSC:

- Quality of goods or services.
- Availability of goods or services which takes into account of supplier's geographic location.

- Supplier service and responsiveness which includes flexibility of supplier to respond to request.
- Cost efficiency by assessing price offered by supplier.

In addition to the above, assessing certifications from suppliers such as the ISO14000 (environmental management), which provide a guideline for firms that need to systematize and improve their environmental management efforts, the right attitude that supplier possesses to sustain the relationship, as well as periodically assessment through audit and monitoring actions are key elements in ensuring a successful supplier relationship (Brammer, Hoejmoose & Millington, 2011; Gimenez & Tachizawa, 2012).

Typically, supplier is expected to produce quality products at reasonable prices; however additional requirement that differentiate supplier selection in the 1MSC concept is the value added capabilities possess by the suppliers. Key differentiator of good supplier is the service that it provides. In the 1MSC context, all suppliers are all linked tightly under the NDI umbrella and deploy collaborative and strategic partnerships.

Cross-sourcing is an ideal solution to ensure no disruption of flow in the chain. According to Eltantawy, Giunipero, & Handfield (2014), cross sourcing can be achieved by having a pool of qualified supplier with same capabilities but each focusing on different segments, if anything would happen to supplier A for instance, supplier B has the capability to produce the same products and vice versa. All these potentially address supplier's competence requirement in SCI implementation.

Manufacturer

Manufacturers are required to register with the NDI in order for these firms to utilize the facilities that 1MSC has to offer as well as registering with government bodies such as the Ministry of Domestic Trade, Cooperative and Consumerism

(MDTCC). Manufacturing context in the 1MSC covers the SMEs and the MNCs. An ideal vision of the 1MSC is for the NDI to develop notable SMEs which have the competences to produce goods with high quality and globally exported. Where "Simplify, Focus and Integrate" is concerned, an intervention by the government in providing incentives, training and supports to the local SMEs is an important aspect for this concept to be realized as the initiative by the government will be able to assist the SMEs to compete both locally and globally (Zhang et al., 2015). It is also responsible to offer facilities and services to the players in the integrated chain such as training, equipment installation, SCM training and courses, IT support, retail and technical expertise. This is aligned to the need of education and re-training system that Sheng (2010) highlighted which will be benefiting the SMEs.

The MNCs is part of the integration as well where the MNCs provide job opportunities to locals. As a result, SMEs produces high level assembly and supplies the parts to MNCs, who has the ability either to produce its own finished good or enables the products to operate with its parts. In return, the Malaysian Government is offering tax relief to MNCs that wishes to make Malaysia a principal hub for their regional operations as well as other incentives for development in undeveloped areas, incentives for industrial area management and capital allowance to increase automation in labor-intensive industries (Mahalingam, 2015). Under NDI's supervision, business operation standards would potentially be maintained across different industries.

For products related to food and beverages (F&B) for instance, the firms must obtain certification from Department of Islamic Development Malaysia (JAKIM) and Ministry of Health (MOH) to ensure that the products sold are safe for consumption or usage, or the food is halal and certified by JAKIM. Firms must also adhere to regulation and audit as it validates that the process performed matches the stated procedure.

Distribution Channel

NDI is responsible to integrate distribution channel, where firms engage in logistics, warehousing and communication. The ideal concept in 1MSC context is to have a selection of logistics providers. Applying the integration concept, logistics activities need to be conducted with systematic approach within an interdepartmental context and closely integrated with external bodies such as shipping and freight agencies. A company's logistics strategy needs to be closely aligned with the supply chain's overall strategy. According to Ajmera & Cook (2009), outsourcing the overall SCM function to a designated third party, called fourth-party logistics (4PL) could provide greater expertise and a broader perspective as it serves a large number of customers across different supply chains. 4PL differs from 3PL as it is often a separate entity from the clients, acts as the point of contact between many logistics providers and its customers, as well its supply chain are managed by the 4PL. The integration could increase the effectiveness of information sharing with available advanced information technology (IT) infrastructure. This would address the challenge in handling logistics and ensure customers' needs are fulfilled accordingly.

Kedai Rakyat 1Malaysia (KR1M)

Another player under the NDI is the KR1M which operates in mini market format providing various basic necessities at low prices. The objective of KR1M is ensuring prices of goods are controlled and reducing the monopolization of global manufactured products. Referencing the 1MSC concept, in the context of supplier selection, NDI is responsible to provide list of SMEs that are able to manufacture products for KR1M. Those individuals or firms that would like to be part of the KR1M operation, has to register with government agency which is the MDTCC. Furthermore, since KR1M offers staple goods and basic necessities, it is compulsory for KR1M owners to obtain ap-

proval from JAKIM and MOH. This is to ensure the quality and safety of the products. The process between KR1M and other firms selling goods and services are not similar. The conventional firms do not need to obtain approval from government for operations. However, since the aim of KR1M is to offer cheaper and quality products to Malaysian consumer, it is understandable for KR1M to obtain these approvals. Cheaper is somehow associated with lack of quality and low safety standards. Thus, KR1M is a unique element of 1MSC.

BENEFITS OF 1MALAYSIA SUPPLY CHAIN (1MSC)

As outlined by Zailani (2011), the objective of 1MSC is to reach sustainable development be it for society, economic or environment. Currently, it is not compulsory for firms to model their business towards sustainable development. However, the acceptance of society and government encourages firms to think about environment, social as well as economic contributions. A sustainably IMSC concept is aimed to achieve the following:

Society

Satisfied customer is an important determinant of repurchase intention (Liao, Palvia, & Chen, 2009) and customer loyalty (Eggert & Ulaga, 2002). In the context of 1MSC, KR1M is expected to supply high quality products with reasonable price resulting in customer satisfaction. The players in 1MSC join forces to meet social needs by empowering consumers in Malaysia through opening its door to society to operate their own business. KR1M also offers society to open KR1M all around Malaysia to ensure everyone is able to purchase quality and cheaper products. Furthermore, KR1M, SMEs and MNCs are into the same network and would possibly able to penetrate international market through exports and adhering to regulations to fulfill international standards. Another unique factors that 1MSC able to offer is the contribution

to the humanitarian aid. Since this notion integrates all players in the supply chain such as the government agencies and distribution channels, 1MSC is expected to pull its players to be able to contribute back to the Malaysian government such as during flood. KR1M for instance will be able to contribute by providing and distributing much needed relief items such as food supplies, hygiene kits and blankets to affected communities.

Economy

The concern of increasing income inequality in Malaysia has become topical. Since the New Economic Policy in 1971, the Malaysian government has regularly executed development strategies by “growth with equity” resulted in the remarkable growth and structural revolution of the Malaysian economy and a substantial reduction in income disparity, however, these strategies which have successfully lessened the poverty rates in the rural sector; but has worsened the income inequality a few decades later (Saiful Nathan & Mohamad, 2016). Since 1MSC focuses in providing opportunity to SMEs, this notion is expected to contribute to economy growth by solving income disparity among society. The KR1M effort to open opportunity nationwide for the people to be part of the network chain is one way to reduce the unemployment issue. By reducing the gap and enabling firms to invest back into the economy through consumption, Malaysia economy will be in a much better shape.

Environment

In the context of environment, the 1MSC is estimated to enforce the need for ISO certification for the players. According to Murray (1999), when a firm gains ISO 14001 certification, it is one way to demonstrate to its customers, suppliers, competitors and the regulators that it is serious about environmental stewardship. With NDI overseeing the 1MSC processes, firms are expected to adhere

to the standards and procedure that the government that sets in.

SOLUTIONS AND RECOMMENDATIONS

The previous sections suggest the concept of 1MSC lies at the NDI's formation. Hence, this chapter recommends the government to build NDI to be resourceful in supporting the 1MSC concept. With NDI as the backbone of 1MSC notion, Malaysian government could implement 1MSC concept to a specific industry to test its effectiveness before proliferating to other industry. In order to be effective, once NDI is established it must be a policymaker to define the guidelines and incentives and enforcement has to be made by the authority.

Another recommendation is to create cluster based economic activities which gathers the experts in the same industry. With the success of KR1M, another recommendation is to create an ecosystem for entrepreneurship with the appropriate skilled labor and talent. This would encourage more individuals to become entrepreneur, hence contributing to the sustainability development.

The success of 1MSC concept can be geared towards the implementation of global SCI as well as achieving supply chain performance. The goal is to deploy one integrated, but globally dispersed, value chain or network that serves the entire worldwide business. With the introduction of 1MSC, firms in Malaysia can compete globally, hence supporting the notion of supply chain versus supply chain. Hence, integration between local and global players depends on the successful factors of 1MSC.

FUTURE RESEARCH DIRECTIONS

There is a need for further research to capture the characteristics of successful 1MSC implementa-

tion to other industry. This is to test if the concept is able to be replicated and accepted globally. It is also worthwhile to study the factors determining the level of 1MSC implementation. The concept of 1MSC is not extensively explored, thus any gaps has to be filled with further research. The impact of 1MSC on business performance and challenges associated with it could also be researched and explored further.

CONCLUSION

In current economic situation, firms create and integrate their own network. Implementation of such individual integration by the respective firm causes an issue where the firm may not have adequate knowledge, resource and funds to face global challenges. The 1MSC addresses this issue by having a nationwide integration and governs by the NDI. With this setup in place it is hoped that the firm will have adequate skills and resources which would enable firms to produce and maximize firms' output. The increment in individual output will increase the nation's GDP. This ensures sustainability in terms of social, environment and economic which relates back to 1MSC objectives and achieve the overall NEM objectives.

KEY TERMS AND DEFINITIONS

1 Malaysia Supply Chain: Collaborated and moved towards meeting the needs of all its stakeholders and providing platform to support business to improve value chains and improving sustainable practices.

Kedai Rakyat 1 Malaysia: Mini market format providing various basic necessities at low prices.

National Development Incubator: Governing body that oversees the integration of all key players.

New Economic Model: Malaysian plan to increase per capita income.

Supply Chain Integration: Information, coordination, and organizational linkage across supply chain activities among partners.

Supply Chain Performance: Outcome of supply chain activities among partners.

Sustainable Development: Achieving goal for social, economy and environment.

A Review of Advances in Supply Chain Intelligence

Nenad Stefanovic

University of Kragujevac, Serbia

Danijela Milosevic

University of Kragujevac, Serbia

INTRODUCTION

As the market pressures are forcing supply chain organizations to adapt to new business models, collaboration, integration and information sharing are becoming even more critical for the ultimate success. Supply chains are experiencing a major structural shift as more organizations rely on a community of partners to perform complex supply chain processes.

While supply chains are growing increasingly complex, from linear arrangements to interconnected, multi-echelon, collaborative networks of companies, there is much more information that needs to be stored and analyzed than there was just a few years ago.

Supply chains are complex systems with silos of information that is very difficult to integrate and analyze. The best way to effectively analyze these disparate systems is the use of business intelligence (BI). The ability to make, and then to process, the right decision at the right time in collaboration with the right partners is the definition of the successful use of BI (Stefanovic & Stefanovic, 2009).

During the past two decades companies have made large investments in supply chain management (SCM) information systems in order to improve their businesses. However, these systems usually provide only transaction-based functionality and mostly maintain operational view of the business. They lack sophisticated analytical capabilities required to provide an integrated view of the supply chain (Baars et al., 2014).

Supply Chain Intelligence (SCI) is relatively new initiative that provides the capability to improve supply chain performance by utilizing sophisticated analytical tools and collaborative decision making (Haydock, 2003). SCI takes broader, multidimensional view of supply chain in which, using patterns and rules, meaningful information about the data can be discovered. Supply chain intelligence reveals opportunities to reduce costs and stimulate revenue growth and it enables companies to understand the entire supply chain from the customer's perspective (Stefanovic et al. 2007).

Nevertheless, companies that implemented some kind of enterprise business intelligence systems still face many challenges related to data integration, storage and processing, as well as data velocity, volume and variety. Additional issues include lack of predictive intelligence features, mobile analytics and self-service business intelligence capabilities.

In this chapter the latest supply chain management issues, and the drivers for the implementation of the business intelligence and performance measurement systems are discussed. Review of the most important literature and research findings provides condensed view of the existing state of the art. Additionally, the latest software technologies and tools, and their impact on different supply chain areas such as collaboration, integration, and analytics are described.

Furthermore, the integrated supply chain intelligence system that enables creation of pervasive

analytical systems for collaborative planning, monitoring and management of the supply network is described. This includes architecture, main components, technologies and tools. The SCI system is robust and cloud-based, capable to handle big data analytical tasks. Its flexible and multilayered architecture enables creation of adaptive supply chain intelligence systems by composing various analytical software components, services and tools. Finally, the main trends and advanced information technologies that will shape the future SCI systems are introduced.

BACKGROUND

Today, there are variety of business initiatives and technologies such as joint planning and execution, business intelligence, performance management (PM), data mining and alerting that can be used for more efficient supply chain management.

By applying the concepts of business intelligence to data from SCM systems, SCI technologies seek to provide strategic information to decision makers (Reddy, 2004). Information categories range from what-if scenarios for reconfiguring key functions in sourcing, manufacturing, and distribution to measuring the ability of a supply chain to produce cost-effective products. Table 1 summarizes the main differences between the SCM and SCI systems (Russom, 2010).

What truly differentiates SCI from BI is the ability to collect and aggregate data across the value chain. Data is then analyzed and the results distributed to all parties along that chain, regardless of location.

SCI technologies promise to extract and generate meaningful information for decision makers from the enormous amounts of data generated and captured by SCM systems. SCI complements supply chain planning because BI applications provide incremental benefits while a business lays the foundation for more sophisticated tools and related business process changes.

Table 1. Comparison of SCM and SCI

Supply Chain Management	Supply Chain Intelligence
Largely about managing the procurement and production links of the supply chain	Provides a broad view of an entire supply chain to reveal full product and component life cycle
Transactional	Analytical
Tactical decision making	Strategical, tactical and even operational decision making
Helps reduce costs through improved operational efficiency	Reveals opportunities for cost reduction, but also stimulates revenue growth
Usually just the SCM application's data (as a vertical stovepipe)	Integrates supplier, manufacturing and product data; possibly syndicated data, too (horizontal)
Records one state of data representing "now"	Keeps a historic record and makes predictions
Assists in material and production planning	What-if forecasting based on historic data
Quantifies cost of some materials	Enables an understanding of total cost
Shows today's yield but cannot explain influences on it, thus provides no help for improvements	Drills into yield figures to reveal what caused the performance level so it can be improved
Simple reporting	Collaborative environment with personalizable monitoring of metrics

The primary source systems for BI are the internal operational systems, while SCI integrates data from partner and supplier information systems. What truly differentiates SCI from BI is the ability to collect and aggregate data across the value chain. Data is then analyzed and the results distributed to all parties along that chain, regardless of location.

Several factors are driving the demand for BI within the SCM domain. First, organizations want more granular visibility to their SCM processes so they can manage and control them more effectively. They also want to identify negative trends in supply chain performance, and identify root causes as early as possible to take corrective action. And they need to conduct 'what-if' analyses to evaluate the service and cost trade-offs of different supply

chain strategies and tactics (Partridge, 2013). The findings suggest the existence of a statistically significant relationship between analytical capabilities and performance (Trkman et al., 2010).

Business intelligence within the supply chain improves internal efficiencies and accountability while saving time and eliminating costs with metrics-driven decision-making and change management. It allows companies to enable more predictable business performance by putting actionable information into the hands of key decision makers (Dowse, 2015).

Most BI implementations are plagued by barriers that limit the strategic value of BI as a building block of the real-time supply chain. Most organizations have experienced the following pitfalls (Lim et al., 2013).

- There is no well-established enterprise architecture for business intelligence.
- Almost all of these tools are based on client/server architectures rather than the Web.
- Data access and the exclusive reliance on a data warehouse.

Having in mind all these drawbacks, as well as large expectation of the BI systems, a new generation of BI systems called BI 2.0 was introduced. The main characteristic of the BI 2.0 system are (Taylor, 2007):

BI 2.0 Integrates Events: BI systems perform event monitoring and react according to predefined business rules, which are prerequisites for the real-time supply network and automatic alerting.

BI 2.0 Delivers Insight: It is not only enough to deliver information via reports, but also to provide business users with additional analytics and instructions for next steps.

BI 2.0 Delivers Action Without Intervention: Based on the embedded expert system, corrective action without human intervention can be taken.

BI 2.0 is Real-Time: Probably the single most agreed feature - all of this must be in real-time or close to it.

BI 2.0 is Based on SOA and Web 2.0: Like most things new BI 2.0 is expected to be service-based and Web 2.0 technologies are expected to impact the user interface for BI 2.0.

In order to achieve required supply chain agility and adaptivity, it is necessary to use intelligent technologies and tools which enable monitoring and evaluation of supply chain performance. Supply chain requires that member companies have the means to assess the performance of the overall supply chain to meet the requirements of the end customer. In addition, it is necessary to be able to assess the relative contribution of individual member companies within the supply chain. This requires a performance measurement system that can operate not only at several different levels but also can link or integrate the efforts of these different levels to meet the objectives of the supply chain.

SCM, has received a remarkable attention from both academia and industry since the last decade, however, there is still lack of integration between SCM systems and performance management systems. The huge majority of performance measurement models and frameworks has focused on single organizations or cover specific type of performance such as financial. There are several performance measurement approaches specifically designed for the supply chain management domain (Chan et Al., 2006). Companies have to measure performance at strategic, tactical and operational levels with metrics dealing with sourcing, making, delivering and customer services (Gunasekaran, 2004).

The main goal of supply chain PM systems is business process optimization through monitoring and analysis of Key Performance Indicators (KPIs). These performance measures enable supply chain companies to align processes and activities with strategic objectives. Key performance indicators are normally backward-looking

because they are based on historical information and often do not help in forecasting future events or performance (Lappide, 2010). Predictive metrics would make possible to predict future problems in supply chain operations and to enable proactive evaluation and improvement actions in advance. Statistical modelling and data mining under the guise of predictive analytics have become critical building blocks in setting the new KPI standard for leading indicators (Gunasekaran et al., 2016).

There has been lot of research efforts during the last decade that deal with various aspects of supply chain performance management. Shepherd and Gunter provide taxonomy of supply chain performance measurement systems and metrics with critical review of the contemporary literature (Shepherd & Gunter, 2006). The study shows that despite substantial advances in the literature in the last decade, there are still important topics related to supply chain performance management that did not receive adequate attention, such as process modeling, data integration, software support, and forecasting. Estampe et al. (2013) provide analysis of various supply chain performance models by stressing their specific characteristics and applicability in different contexts, so that decision-makers can evaluate and apply models and metrics that best suit their needs. Akyuz and Erkan (2010) also provide a critical literature review on supply chain performance measurement. The results show that performance measurement in the new era is still an open area of research. This particularly refers to framework development, collaboration, agility, flexibility, and IT support systems. Gopal and Thakkar (2012) contribute a comprehensive review of supply chain performance measurement systems. The analysis shows that in spite of considerable evidence from the literature, there is a large scope for research to address critical issues in supply chain performance measurement, including: metrics, benchmarking, integration, business intelligence, and collaborative decision making.

The resolution to these problems can be integration of different BI and PM tools and technologies into the supply network collaboration infrastruc-

ture based on Internet technologies. This means packaging analytical and PM applications into corporate portal that business users can access online and then allowing them to share not just the static output, but also the actual dynamic analytical experience through online collaboration.

In the following section, a comprehensive supply chain intelligence model and its realization through a specialized SCI web portal which acts as a unique gateway to different information sources and provide services for supply network coordination, planning, analysis, monitoring and data mining is presented (Stefanovic, 2011). The model and the supporting software solution are developed having in mind some drawbacks of the existing systems, as well as characteristics of the future SCI systems.

SUPPLY CHAIN INTELLIGENCE MODEL

The core elements of the SCI model are process model with metrics, data warehouse and SCI web portal. The process modeling method and the data warehouse dimensional modeling approach, as well as the layered service-oriented composite web application introduce a new breed of robust and flexible SCI systems that can be relatively easily implemented, customized and personalized. This way, previously separate models, tools and technologies are seamlessly integrated into the complete SCI system.

The integrated SCI model should ultimately provide all the main capabilities required for the successful supply chain management (Figure 1).

BI web portal holds the central place in the model, as it comprises a portfolio of analytic, collaboration and communication services that connect people, information, processes, and systems both inside and outside the corporate firewall.

Supply chain planning subsystem provides a consistent and timely view into a business by using data from existing systems like data warehousing (DW) or On-Line Analytical Processing (OLAP)

Figure 1. Capabilities of the SCI System

cubes, without changing those systems. It provides centrally managed data, business metadata, business rules, business logic, views, forms, report definitions, process control, and security.

Data mining techniques can be applied to many supply chain applications, answering various types of business questions, such as demand forecasting,

inventory prediction (Stefanovic, 2015), customer and product segmentation, risk management, etc. They can be used also to perform key performance indicators (KPI) predictions in order to take proactive actions (Stefanovic, 2014).

Analytics and reporting subsystem should provide unique tools for decision makers to explore

Figure 2. Supply Chain Intelligence Model

large quantities of data in a way that provides rapid insights. These can include advanced analytic capabilities ranging from multidimensional “slice and dice” to decomposition trees, drill-across, root-cause analysis, self-service report models and information on-demand.

In order to fully realize these SCI capabilities, we need a supply network-wide business excellence model that will provide consistent framework for establishing, modelling, managing, measuring, and improving supply network processes. Figure 2 illustrates the overall supply chain intelligence model.

The proposed SCI model unifies processes, methodologies and tools into a single business solution. SCI model has been developed in such a way to seamlessly integrate within overall BI and collaboration framework (Stefanovic et al., 2011).

The SCI model is process-centric, metrics-based and modular. It introduces the new supply network and data warehouse modeling approaches, as well as layered application architecture which enables creation of composite BI systems.

In contrast to most other BI models that usually approach supply chain from the functional perspective or treat only internal processes, our approach uses the standardized supply chain process model and metrics. The novel process modeling method

enables modeling of any supply network regardless of the number of companies, process types and relationships. Process, metrics, interactions, flows and other elements (for example, resources and constraints) can be modeled at different levels of detail, thus serving as a basis for dimensional modeling, KPI design, simulation and business process management.

The dimensional modeling method offers best practices and design guidelines for developing main data warehouse elements. The unified dimensional model (UDM) serves as an extra layer that isolates business logic and logically unites heterogeneous data sources (such as relational databases, data marts, spreadsheets, web services, etc.) into the single data resource. Also, comparing to traditional DW approaches, the unified dimensional modeling approach allows design of additional DW elements such as complex calculation, hierarchies, measure groups, and KPIs. All the DW elements can be reused as templates since the definitions are stored as XML files. Analytical models can be built in both, traditional multidimensional OLAP and in-memory tabular modes, depending on the business requirements and priorities. This architecture of the model provides scalability and the performance is improved by using the in-memory data store.

The data warehouse approach allows the single version of the truth because of the integrated and consolidated data repository. Server-based definition of KPIs offers centralized metadata management and enables creation of various front-end BI and analytical applications. Data warehouse acts as an integrated data source upon which different BI elements are developed such as planning models, performance monitoring systems, reporting and data mining models.

SCI Web Portal

The main problem with traditional BI tools is problem with delivering information to end-users or other systems. They usually require special client tools, support only certain data sources (for example ERP systems) and they are difficult or impossible to customize or integrate. That is why our SCI model introduces specialized web portals for analytics, monitoring, planning, data mining and simulation. In order to fulfill these functions, BI portal is built as a layered service-oriented application which utilizes the newest web technologies for the special BI tasks.

The concept is based on service-oriented architecture, models and templates, which should enable creation of the new breed of SCI solutions that connects business processes, data, applications, and users into a single integrated system.

The idea is to define BI service-oriented architecture which provides a standard and flexible approach for integration of business processes, analytics, information, business transactions and collaboration tools. This approach enables separation of business processes and applications, and creation of data, application, and collaboration services on demand and based on events. These services can be further arranged into composite BI applications for particular business processes and activities.

In order to overcome the shortcomings of the existing BI and PM client tools, the specialized web portal that enables supply chain users to monitor business processes, collaborate and take

actions is designed (Stefanovic & Stefanovic, 2011). It has been successfully implemented as a pilot project in an automotive company. Automotive supply chain is typically very complex, with many organizations, intertwined processes, and multitude of users with different requirements.

The portal represents a single point of access to all relevant information in a personalized and secured manner. Its composite and service-oriented architecture enables inclusion of different PM components and tools (KPIs, dashboards, scorecards, strategy maps, reports, etc.). PM elements can be personalized and adjusted, and information can be filtered just by using a web browser. PM elements can be defined within the portal and also embedded from the external source (OLAP, another application, spreadsheets) via web services. This information is presented through special analytical web parts. The portal itself can be a provider (via web services or RSS-Really Simple Syndication) to other applications.

BI portal is a composite web application made of certain elements. Elements can be viewed at four distinct layers: presentation layer, collaboration layer, application layer and data layer. The portal is modular and each module can be modified and customized and also new modules can be added, thus assembling composite BI applications that fit specific user needs.

Modular architecture of the portal enables creation of various BI mashups tailored to specific business needs. Web parts, pages and also the complete portals can be saved as templates and reused many times with minimum effort.

Figure 3 shows the analytical dashboard page with different web parts that display key performance indicators, charts and graphs. Each web part can have different data source such as OLAP KPI, spreadsheets, report server, web portal database data feeds, etc. Since each data source can reside at different supply chain company, there is a specialized data gateway that acts as a bridge, providing quick and secure data transfer and refresh between the analytical service and on-premises data sources. Such dashboards and

Figure 3. SCI Dashboard Page

reports can be embedded in SCI portals along with other BI web parts thus composing flexible and customized analytical solutions.

A system of templates and taxonomies enables creation of a number of hierarchical portals. For instance, it is possible to create a global supply network BI portal, several company-level BI subportals, and many division-level subportals.

Additionally, the portal supports events and automatic alerting. Users can subscribe to specific documents or keywords and KPIs, to be notified when metrics are updated or new intelligence becomes available. They can also use other features, such as planning, enterprise search, subscription,

and routing functions, to work with team members on a single item (i.e. scorecard, KPI, etc.), and to automate collaborative performance management processes. The portal also provides fine-grained authentication and authorization.

On the other hand, software system architecture enables relatively easy and fast customization and extensibility. For example, existing KPI components can be easily reused many times, and only needed items can be added to web sites and pages. Also, a new (custom) lower-level metrics can be defined in the SCM Metamodel and realized in the data warehouse, thus allowing company-specific and industry-specific performance measurement.

Self-service BI is enabled through the incorporation of particular analytical models that enable end-users to create various reports and queries without additional intervention of the IT staff.

All these capabilities make the proposed SCI model and the software system extremely flexible, and applicable in various supply chain scenarios and different industries. Being based on the SCM Metamodel and standardized metrics, ensures general applicability (in various business domains) (Stefanovic & Stefanovic, 2008).

By implementing the presented BI portal it is possible to deliver insights to the right person, any time, via any device and in a secure manner. Personalization and filtering capabilities enable end users to access information relevant to them. All this features allow supply chain partners to bring more informed decision collaboratively.

FUTURE RESEARCH DIRECTIONS

As financial analysts have pointed out (Gartner, 2009), the BI software segment is a bright spot in the software industry and continues to grow even during the world economic crisis. BI is ranked as the highest technology priority among CIOs. On the other side, SCM market also continues to grow and the number of companies who adopted and implemented SCM concepts and systems constantly increases. These trends will certainly boost the demand for the SCI set of processes, technologies and tools.

Besides holding a huge market, these technologies have been the subject of intense academic research and study. As an interdisciplinary science field, SCI will certainly be one of the very active research topics in the years to come, since it comprises various operations management disciplines and IT domains like business intelligence, big data, collaboration, service-oriented architecture, cloud technologies and web portals.

In the next few years, research and development in BI domain is expected to rise. The main

advances can be grouped into the following categories (Gartner 2016):

- Infrastructure (cloud BI, security and user administration and data source connectivity).
- Data management (governance and meta-data management, self-contained extraction, transformation and loading (ETL), and data storage, self-service data preparation).
- Analysis and content creation (Embedded advanced analytics, analytic dashboards, interactive visual exploration, mobile exploration and authoring).
- Sharing of findings (embedding analytic content, publishing analytic content, collaboration and social BI).

In this era of Big Data, even while BI 2.0 is still maturing, BI 3.0 is on the way. BI 3.0 provide high performance analytics with in-memory technologies, and put emphasize on social networking, collaboration, as well as ubiquitous and assistive analytics. These new and potentially revolutionary technologies present a great opportunity for research and development for both industry and academia (Schoenherr & Speier-Pero, 2015).

CONCLUSION

To succeed in a competitive marketplace, an agile supply chain requires SCI system to quickly anticipate, adapt, and react to changing business conditions. SCI systems provide sustainable success in a dynamic environment by empowering business users at all levels of the supply chain and enabling them to use actionable, real-time information.

Many of forward-thinking supply networks have realized that business intelligence networks are a first step to information consolidation and gaining visibility over the value chain. With BI networks, businesses can share information with customers, suppliers, and partners.

The presented SCI model fuses all relevant elements such as people, business processes, metrics, KPIs and BI tools into a single comprehensive system. The underlying architecture supports the complete cycle of BI/PM processes like ETL, DW, OLAP and reporting. The unified data model helps to establish a single version of the truth on supply network performance, which is quantifiable and understood by all entities in the supply network.

SCI web portal is the unifying component that provides integrated analytical information and services, and also fosters collaborative decision making. The portal offers the following benefits:

- Real-time supply network monitoring and alerting.
- Flexibility, personalization and customization.
- Integration with existing transactional, BI and collaboration systems.
- Built-in knowledge and best practices through predefined web parts and templates.

The proposed layered SCI architecture allows construction of the next-generation loosely-coupled SCI networks that are built as BI web services. This will enable collaborative, efficient, responsive, and adaptive supply chains.

KEY TERMS AND DEFINITIONS

BI Portal: A specialized web portal that provide a range of analytical services and which enables collaborative decision-making.

Business Intelligence: A set of processes, technologies and tools comprising data warehousing, On-Line Analytical Processing, and information delivery in order to turn data into information and information into knowledge.

Data Mining: Set of knowledge discovery techniques for intelligent data analysis in order to find hidden patterns and associations, devise rules and make predictions.

Data Warehouse: An integrated data repository system for extracting, loading and transforming data into information.

Performance Monitoring: Methodology to optimize the execution of business strategy through the real-time and proactive performance measurement and management of the supply network that consists of a set of integrated, closed-loop technologies and tools such as scorecards, key performance indicators, and business activity monitoring.

Supply Chain Intelligence: Process of integrating and presenting supply chain information in order to provide collaborative planning, monitoring, measurement, analysis and management of the supply network.

Supply Chain: Dynamic, interconnected and collaborative group of companies working jointly on planning, management and execution of cross-company business processes spanning from the first tier suppliers to the end-customers.

A Review of Supply Chain Risk Management in Agribusiness Industry

Sri Widiyanesti

Telkom University, Indonesia

Yudi Fernando

Universiti Malaysia Pahang, Malaysia

INTRODUCTION

There will always be risk in business. Nowadays, to be able to run business and succeed, companies should be able to identify risk factors and minimize the risks involved. The biggest challenge now is not only identifying and minimizing risk factor in the company's internal, but the risk factors in the company's supply chain network, in both upstream and downstream activity. Companies that are not able to handle the risks that arise in their business will inevitably suffer losses.

Facing increasing global competition and the fact that supply chains become more complex, there is a possibility that increasing the performance of supply chains will be difficult to reach, mainly because of the failure risk of supply chains (Tumala and Schoenherr 2011).

Companies that will able to survive is those resilient enough in managing risks. Risks that would be faced by companies are very diverse, depending on the company's business type. For example, the iron industries in India have risks and problems such as; short life cycle and season ability, supplier inefficiency, design and technological changes, union strike, fluctuations of demand, lack of ownership, capacity and information, inventories, corporate strategy and goal, implications, and customer uncertainty (Pradhan and Srikanta, 2014).

Indonesia is the largest archipelagic country in the world and agricultural lands are widely available in Indonesia. Furthermore, most of

Indonesians are working in agricultural sector. Agricultural sector is a critical industry to support daily life and food consumptions of Indonesian population. With such conditions and demands, Indonesia should be the world's agricultural source, but, ironically, it is a frequent occurrence that Indonesian depends on imported agricultural products including nine basic commodities rather than produce its own demands for food source.

Supply chain of agricultural commodities become a major concern of Indonesian scholars and practitioners. Many companies engaged in this industry unable to survive in the long term. This is an unfortunate condition because Indonesia has abundant natural resources and plenty of commodity producers.

The development of industry and services sectors have a significant impact on the amount of agricultural land that is converted industrial and residential areas (Trisnasari et al., 2010). Indonesia is facing a decline in agricultural land area of about 2.65% (Pertanian.go.id, 2014). Agricultural land in Indonesia are switching functions, fields and rice paddies are being converted to housing and offices. This decline in agricultural area contributed to the decline of food production, which led to Indonesia importing agricultural products.

Aside from the reduced agricultural production, agriculture is no longer a major contributor to Indonesia GDP. In 2012 to 2014, the percentage of agricultural GDP decreased if compared with trade and processing industry (BPS, 2015). Despite being forecasted that in 2017 Indonesia

will become self-sufficient in food production (Gera, 2015), it cannot be achieved if agricultural production has declined.

Indonesia has abundant natural resources adequate for agriculture, but unfortunately agriculture cannot be a source of revenue for Indonesia. The government must begin to focus on agriculture, because Indonesia has the resources, community livelihood, and agricultural fields. Besides agriculture is the primary food source for Indonesia, and a major needs worldwide.

Indonesia archipelago is unique compared to other agribusiness countries, such as Thailand. The problem faced by Indonesia is more complex, especially problems in the distribution and transportation sector. Besides Indonesia is experiencing other problems that hinder the development of agribusiness in Indonesia. With the current condition of Indonesia, farmers face a variety of business risks. Companies that will able to survive is those which resilient in managing risks. Risks that would be faced by companies are very diverse, depending on the company's business type.

The literature review was a synthesized and limited articles published on supply chain risk management in agribusiness industry. It mostly has been discussed regarding supply chain risk management in manufacturing industry. The lack of studies to investigate the risk factors in agribusiness will make this study a contribution to the supply chain literature. This is because the managing risk in supply chain in agribusiness industry could be different compare to manufacturing industry.

BACKGROUND

Supply chain management is an overall coordination of supply chain activities including the improvement of customer value (Heizer and Render, 2015).

Supply chain management will improve companies' performance. In supply chain management, companies will get challenges from risks that pos-

sibly would be faced by the company. Companies must be able to know the risks, therefore, could interfere in business resilience.

Risks that arise in the supply chain can negatively impact supply chain performance. Companies must have a strategy to manage the risks, so that effectiveness can be achieved (Giannakis and louis, 2010). This can be evidenced by an example of a toy company that faced lawsuits and must withdraw the toy because of the supply chain failure due to a risk emergence in the supply chain (Story, 2007; Tumala & Schoenherr, 2011). For a manufacturing company producing pencils, supply chain risks that may arise are demand, delay, disruption, inventory, manufacturing, capacity, supply, system, sovereign, and transportation problem (Tumala and Schoenherr, 2011).

According to Thun and Hoenig (2009), supply chain risk is divided into external and internal risks. Internal supply chain risks consist of supplier failure, malfunction of IT systems, supplier quality problems, change in customer demand, machine breakdowns, increasing raw material prices, transportation failure, disruption of the delivery chain, and technological change. While the external supply chain risks, for example, in manufacturing firms in German are accident, strike, war, natural disaster, import restriction, oil crisis, terrorist attacks, and increasing customs duty.

The definition of demand risk in supply chain is the order fulfilment errors, inaccurate forecasts due to longer lead times, product variety, swings demand, seasonality, short life cycle, and small customer based on information distortion due to sales promotions and incentives, lack of supply chain visibility, and exaggeration of demand during product shortage (Tumala and Schoenherr, 2011). While other researchers assert that demand fluctuations and customer demand uncertainty is also included in the demand risk in supply chain (Pradhan and Srikanta 2014).

Delay risks occur due to excessive handling in border crossing or change in transportation mode, port capacity and congestion, custom clearances

at ports, and transportation breakdowns (Tumala and Shoenherr, 2011).

Disruption risks include natural disaster, terrorism and wars, labor disputes, single source of supply, capacity and responsiveness of alternate supplier (Tumala and Shoenherr, 2011). While inventory risks include a cost of holding inventories, demand and supply uncertainty, rate of product obsolescence, and supplier fulfilment (Tumala and Shoenherr, 2011). Pradhan and Routray (2014) mentions several categories of risk that may occur in the supply chain in the iron industry in India which is short life cycle, capacity and information, season ability and, inventory.

Manufacturing (process) breakdown risks include poor quality (ANSI or other compliance standards), lower process yields, higher product cost, and design changes (Tumala and Shoenherr, 2011).

Physical plant (capacity) risks include the lack of capacity flexibility and capacity cost (Tumala and Shoenherr, 2011).

Supply (procurement) risks include delivery performance, supplier fulfilment errors, selection of wrong partners, high capacity utilization supply source, inflexibility of supply source, poor quality or process yield at supply source, supplier bankruptcy, rate of exchange, percentage of a key component or raw material procured from a single source (Tumala and Shoenherr, 2011). Pradhan and Srikanta (2014) mentions a number of categories of supply risks that may occur in the supply chain in the iron industry in India which include supplier inefficiency and early supplier involvement. Also the bigger risks in supply companies are characteristics of supplier and supply disruption.

System risks include information infrastructure breakdowns, lack of effective system integration or extensive system networking, and lack of compatibility in IT platforms among supply chain partners (Tumala and Shoenherr, 2011). Another study states that design and technological changes are included in system risks (Pradhan and Routroy, 2014).

Sovereign risks include regional instability, communication difficulties, government regulations, loss of control, and intellectual property breaches (Tumala and Shoenherr, 2011). Meanwhile according to Pradhan and Srikanta (2014), included in sovereign risks are corporate strategy/goal and union strikes.

Transportation risk include paperwork and scheduling, port strikes, delay at ports due to port capacity, late deliveries, higher costs of transportation that depends on transportation mode chosen. (Tumala and Shoenherr, 2011).

There are three classifications of risks in supply chains, the first is the risk in information security. Information security risks can be defined as the risks associated with sharing information with external agents. The second is a supplier opportunism which means suppliers act in their own interest by deliberately withholding or distorting information. The third risk is corporate social responsibilities, which occurs when suppliers do not pay attention to social and environmental demands (Spekman and Davis, 2004; Ellegaard, 2008).

According to David L. Olson and Wu Desheng (2011) there are several categories of risk that may occur in the supply chain of China's outsourcing strategy which are accounting, asset impairment risks, country risks, competitive risks, customer risks, downside risks, financial risks, interaction, legal risks, product risks, regulatory risks, reputation risks, shared risks, and supplier risks.

According to Telman and McCormack (2009) companies' risks are divided into two categories, namely continuous risk and discrete risk. Continuous risk is a potential event that raises cost continuously and relatively easy to predict. Discrete risks is a high-impact events which can be classified as terrorism, the spread of diseases, and natural disaster (Faisal et al, 2006. Telman and McCormack, 2009). Discrete risks are hard to be predicted and measure (Telman and McCormack, 2009).

According to the layout and Revoredo (2013), the risks of supply chains in the livestock industry

are production risks, market risks, and institutional risks.

According to Punniyamoorthy, Thamaraiselvan, and Manikandan (2013) some of the risks of supply chain in the steel mining industry are supply side risks, manufacturing side risks, demand side risks, logistics side risks, information risk and environment risks.

According Tang (2006) supply chain risks are divided into two; operational risks and disruption risks. The operational risks include uncertain customer demand, uncertain supply, and the uncertain costs. While disruption risk is a major disruption caused by both natural and man-made disasters, such as earthquakes, floods, hurricanes, terrorist attack, and economic crisis.

According to Aqlan and Lam (2014), there are nine categories of risks: supplier risk, customer risk, process and control risk, technology risk, product risk, occupational risk, culture risk, transportation risk, and commodity risk.

There are plenty of research on supply chain risk management already. Most of those studies are targeting the manufacturing industry, while we rarely see a study on this matter which is targeting the agribusiness industry. The lack of studies to investigate the risk factors in agribusiness makes this study contribute to enrich the literature on supply chain risk management.

MAIN FOCUS OF THE ARTICLE

Issues, Controversies, Problems

There are problems in the agricultural supply chain which is appeared to be the impact of the condition of commodities in Indonesia. Some of the problems are frequent fluctuation in commodity prices, commodity shortages, rises in seed or feed prices, unbalanced supply and demand, expensive distribution and production costs, the tendency to import raw material commodities, and natural disasters.

Commodity prices in Indonesia are frequently going up and down. It is not uncommon for commodity prices to change—not on a yearly or a semester basis—but on a daily basis. The price fluctuations are tough to manage, even by the Indonesian government. For example, the price of tomatoes initially valued at IDR 9,000 per kilogram; then it suddenly decreased by 44.44% reaching the price of IDR 4,000 per kilogram. For curly red chili, the prices dropped from IDR 80,000 per kilogram to IDR 25,000 per kilogram. As the result, farmers who have invested a tremendous amount of funds suffered a massive loss because of this situation (Wiyoso, 2014). At first, when the farmers have just started planting, the commodity prices tend to be stable. However, when the harvest time comes, the prices dropped significantly. The absence of planting date management in turns creates an unbalanced demand and supply in the market.

As mentioned before, Indonesia has an unbalanced supply and demand on its commodities. For example, one area supply for certain commodities that they produce exceeds demand which makes the price of that commodity, in that particular location, very cheap. Meanwhile, in another area supply fall short on demand, but the price of the commodity is very high. For example, the price of potatoes are variable in every city in Indonesia (BPS, 2015). In cities located in Java region such as Bandung, Cilacap, and Malang, the price of potato is under IDR 10,000. Meanwhile, outside Java the prices tend to be higher than IDR 10,000. These differences were the result of the expensive distribution cost in Indonesia.

There are many factors contributed to the expensive distribution costs in Indonesia, one of them is the transportation fee. The distribution cost in Indonesia is very expensive, even shipping a package from Jakarta to Hamburg (11,000 km) is cheaper than shipping from Jakarta to Padang (1,000 km). Distributing products to areas outside Java cannot be done directly between cities due to inadequate local infrastructures like port and

airports. It means that before the goods are shipped to the destination, it has to be sent to Jakarta first. In addition to problems of coordination between the central government and local governments. In Southeast Asia, Indonesia is one of the countries with the highest transportation costs. Thailand's logistic costs lower by 7 percent of the GDP, while Indonesia's logistic cost is 27 percent of GDP (Suara Cargo, 2015).

In addition to the high distribution costs, agribusiness in Indonesia is also influenced by the cost of production. High production costs are the result of the expensive fertilizer. The government tries to solve this problem by giving subsidies for fertilizers. Shortages of fertilizer are often the case in Indonesia; farmers can obtain the fertilizer, but the price is very high. The fertilizer that cost about IDR 90,000 per kg is sold to the farmers at the price of IDR 125,000 per kg. Apparently, many middlemen pile on the subsidized fertilizer that has been given by the government which forces the farmers to buy the fertilizer with a high price (Mashita, 2015).

The middlemen not only interferes in the distribution of raw material (fertilizer), but also in the distribution of the finished products. It also happens to onion farmers, who complained about the agents who always ask for a commission from the sale of one hundred pounds of onions. Fees paid to the agent is approximately 15% of the total sales (Rofiq, 2015). Such incident increases the selling price of onions in the market and lowers the profit for the farmers because of the high production costs. The middlemen also meddle in the rice industry. Middlemen are reportedly buying rice from farmers and sell it out of town for a higher price (Widiyanto, 2015). This phenomenon triggers the staple crops shortage, even in areas with a granary.

Unfortunately, the government fails to control the middlemen. They had a secure network and even protected by corrupt government officials. Besides the middleman, scarcity of commodities is also caused by the business owner. In most cases, they are reluctant to sell their products to

the market so that they can get a higher selling price. This incident not only occurred in agriculture industry but also in other nine basic commodities industry. For example in beef, the government predicts that there are an adequate amount of cattle at the local farm. Therefore, in the third quarter, the government decided to lower the amount of imported meat. Then, the government is asking the local cattle farmer to sell the cow to the market. However, the farmers are reluctant to sell the cow because usually the policy is issued right before the Eid al-Adha. As the result, some farmers chose to temporarily stop selling his cow in order to get a higher price. The beef meat prices in the market usually cost about IDR 80,000 / kg, but the delay on the sale causes the price to escalate to IDR 130,000 per kg. An increase in beef prices occurred almost throughout Indonesia, including in the area which is the center of livestock such as Madura, Bali, and NTT (Zamzami, 2015).

Increased prices of nine basic commodities in Indonesia happens because of the tendency to import the raw material. One of the examples is soybeans, which is the raw material of tofu. The fluctuation in the value of Indonesian Rupiah against the US Dollar causes the price of these commodities fluctuates. The exchange rate of the Indonesian Rupiah in the last four years is very volatile. In 2011, the exchange rate of the Indonesian Rupiah was at the level of IDR 8,958 per US Dollar, and in 2015 it was at IDR 14,467 per US Dollar. It appears that from 2011 to 2015 the exchange rate of the Indonesian Rupiah against the US dollar increased by 64.55. It eventually leads to a significant increase in the price of imported raw materials and the selling price of commodities like tofu (Aimon and Satrianto, 2014).

Natural disasters are also the cause of shortages in nine basic commodities. For instance, the eruption of Mount Sinabung in North Sumatra led to the scarcity of vegetables in the year of 2013. Supplies of whole vegetables in the nation reportedly decreased from 30% to 50%. The eruption of Mount Sinabung inevitably halted the farmers' activity because they have to evacuate to shelters.

As the result, farmers temporarily stop growing vegetables which lead to a vegetable shortage in Indonesia (Medan Bisnis, 2015).

In addition to volcanic eruptions, floods may also cause a shortage in commodities. Because of the flood, the farmers often have to face a devastating crop failure. For example, in the year of 2014, floods soak the rice fields in the area of Cirebon, West Java. The flood in this area was caused by high waves in the ocean located in the north of Java (Rachman, 2014). On February 2015, Banten suffered a flood that drowned the rice fields in the area, and the floodwaters itself does not recede within a week. Approximately 3000 hectares of land were flooded, and this may interfere with the availability of food in Banten (Deslatama, 2015). Besides that, flood often occurs in the capital city of Indonesia, Jakarta. The disaster left the economic and trading activities in the country paralyzed. If Jakarta floods, it will affect the distribution of the commodity in Indonesia, because the distribution is always centered in Jakarta. The losses suffer because of the floods that hit Jakarta is approximately 30 percent of the total distribution losses for the whole of Indonesia (Syahputri, 2013).

SOLUTIONS AND RECOMMENDATIONS

The problems exist in agribusiness industry in Indonesia are very complex. That explains why there are plenty of companies engaged in this industry that failed to survive. The fact is contradictive with the natural state of Indonesia with its abundant natural resources and plenty of commodities producer. These problems occur because companies are not ready to face the risks which exist in the agribusiness industry.

In Indonesia's agribusiness industry, the price is unstable. The price of commodities constantly fluctuates, and the price also varies from each region in Indonesia. Companies should be able to

deal with this problem. This problem may cause the company to suffer so many losses since the price may be lower than the cost of production. The imbalance between demand and supply can fluctuate price, especially in areas with commodity shortage. This is what we called as demand and supply risk. The lack of inventory may also cause scarcity of commodities in a region; this is because some of the commodities that are limited to particular areas. Agribusiness companies can avoid this if they can manage inventory risk properly.

Supply risk also occurs in the scarcity of manure as a raw material for the process of planting crops. Beside that there is also a shortage of the raw materials (e.g. the scarcity of soybeans as one of the raw materials to produce tempeh and tofu).

Shortages and prices fluctuation in Indonesia happen because of the middlemen who meddle in the distribution process. Apparently, the government finds it difficult to deal with these agents, even though they significantly affect farmers and the market. If the government wants a more stable business, then the government should create a rule that may minimize the sovereign risks. The emergence of powerful middlemen in agribusiness, which is the result of the poorly-managed transactions system, may pose a system risk to agribusiness companies.

The scarcity of commodities is also caused by natural disasters such as earthquakes, floods, and volcanic eruptions. These natural disasters may cause disruption risk in the agribusiness industry. The natural disaster itself is the hardest risk to predict and to avoid. Floods occurred in the capital city of Jakarta often causes delays in delivery and caused shortages in some areas. Risk arising from the flood is called delay risk.

The increased price of commodities in Indonesia is also caused by the tendency to import some of the raw materials from foreign countries. The unstable exchange rate in the transaction may give rise to procurement risk in agribusiness.

High prices of commodities in Indonesia are also the result of high distribution costs in

Indonesia and the delivery system in Indonesia. Commodities sent from an area outside the Java region must go through the capital city because the regions outside of Java do not have adequate port and airport. In this case, the risk faced by the agribusiness company is the transportation risk. Transportation risk, if cannot be anticipated, will lead to increased production costs. This centralizes distribution system makes it longer and harder for companies to receive the commodities. Therefore, it would bring delay risk to the agribusiness companies.

Based on interviews with various companies engage in agribusiness, it appears that there are several risk factors that they often face, which are demand risks, supply risk, delay risks, disruption risks, inventory risks, procurement risks, system risks, sovereign risks, and transportation risks.

SUGGESTION FOR FUTURE RESEARCH

Further research is suggested to discuss how supply chain risk management manages to minimize the risk factors of agribusiness in Indonesia. It can also discuss the dominant factor in Indonesia's agribusiness industry and what steps should be taken by the government to develop agribusiness in Indonesia. In addition to this, it is also recommended to study another type of supply chain risk management which will suit other countries, since Indonesia has unique characteristics compared to other nations in term of agribusiness.

CONCLUSION

This paper concludes that there are nine risk factors occur in the agribusiness industry in Indonesia, which are demand risk, supply risk, delay risk, disruption risk, inventory risk, procurement risk, system risk, sovereign risk, and transportation risk. To survive in this industry, companies which

engage in agribusiness should be able to identify risk factors that may occur in the industry and learn how to deal with them. Therefore, companies need to apply the supply chain risk management to minimize those risks.

KEY TERMS AND DEFINITIONS

Demand and Supply Risk: Demand risk is result from disruption emerging from downstream supply chain operator an supply risk is result from disruption emerging from upstream supply chain.

Disruption Risk: Disruption risk is risk which arise from natural disaster, such as weather disruption, or man made ones such as economic crises.

Sovereign Risk: Sovereign risk is risk which come from Regional instability, Communication difficulties, Government regulations, Loss of control, and Intellectual property breaches.

Transportation Risk: Transportation risk is risk which come from Port strikes, Delay at ports due to port capacity, Late deliveries, Higher costs of transportation, and Depends on transportation mode chosen.

The Role of Emerging Information Technologies for Supporting Supply Chain Management

Zlatko Nedelko

University of Maribor, Slovenia

Vojko Potocan

University of Maribor, Slovenia

INTRODUCTION

Over decades of rapid development of information technology and especially internet it has become apparent that information technology has been significantly influenced all areas of our life and business (Ayeh, 2008; Nedelko & Cirnu, 2008; Stucky & Weiss, 2008). In terms of its impact on business sphere an important viewpoint is related to the supply chains, which has become the center of attention in business literature. This is due to the globalization and the fact that each organization belongs at least to one, in business practice often more, supply chains or networks (Cooper et al., 1997; Beamon, 1998; Lummus & Vokurka, 1999; Christopher, 2011).

A basic definition defines supply chain as integrity of all parties involved, directly or indirectly, in fulfilling a customer's needs. The supply chain includes suppliers, manufacturers, customers, distributors, warehouses, retailers (Chopra & Meindl, 2013, p. 13). In short, supply chain encompasses all entities that are involved in flow of raw materials, through production to the end customer. An important aspect of supply chain management is the exchange of information among partners in the supply chain, which important influence success and agility of the supply chain.

In terms of the exchange of information and especially collaboration among entities in the supply chain, a plethora of solutions, based on modern information technology, are aimed to

enhance the working of entities in the supply chain and enable better exchange of information, goods, services, and collaboration across different entities in the supply chain. Different information technology solutions play an important role in supporting supply chain management in today's organizations and its supply chains. From the viewpoint of solutions, that are based on information technology, at the pedestal are solutions that support customer relationship management (Chen & Popovich, 2003; Tamosiuniene & Jasilioniene, 2007; Kumar, 2010). Besides, that in a contemporary environment, an important viewpoint for enhancing supply chain management, relates to the utilization of emerging solutions, which can be used in order to improve supply chain management in the future.

The main purpose of this chapter is to examine the role, importance and actual usage of emerging information technology solutions that support and have potential to enhance supply chain management in practice (Chen & Popovich, 2003; Rigby & Bilodeau, 2011). The role of information technology in supply chain management is in this paper discussed through the lenses of several selected emerging management tools, like collaborative innovations, corporate blogs, radio-frequency identification, and shared services centers. For a more comprehensive discussion, results for several selected management tools utilization are reported for selected worldwide regions, like North America, Latin America, Asia Pacific, Europe and

DOI: 10.4018/978-1-5225-2255-3.ch483

example two emerging economies from Central and East Europe.

BACKGROUND

There are many possible ways to examine the role of information technology in supply chains (Beamon, 1998; Simchi-Levi et al., 2009; Christopher, 2011; Chopra & Meindl, 2013). In this paper, we adopted an approach that is based on the typical development phases of the supply chain. In that framework we outline typical development phases and the role of information technology in each of these phases. Next, in line with the aims of our paper, we put our focus on examination of the role, importance and actual usage of information technology solutions that support supply chain management and customer relationship management in organizations worldwide.

Supply Chain

Supply chain presents ambitious and strategically significant concept, which can be defined as “managing the entire chain of raw material supply, manufacture, assembly and distribution to the end customer” (Heitzer & Render, 2003; Murphy & Wood, 2004; Christopher, 2011). The supply chain is the most developed integrated concept, but by its use, the organization meets some open dilemmas such as: 1) what sort of connections exist among the part of supply chain, 2) what is the role (meaning) of different units (e.g. parts) in the entire supply chain, and 3) how can we optimize the parts of the entirety (to form structure) to reach “optimal results” of common work.

Due to the crucial importance of cooperation and especially information exchange among entities involved in supply chain, information technology plays a crucial role since it enhances or facilitates exchange of information among entities in the supply chain. In order to emphasize the role of information technology in supply chain, we first outline basic integrated concepts of supply chain

that will serve us for a presentation of the steadily increasing role of information technology, through different phases of supply chain development.

There are many different ways in which the linkage involved in the flow of materials and services can be integrated or grouped together (Rushton et al., 2001; Heitzer & Render, 2003; Slack et al., 2006). Four main concepts will be presented here. These have focused attention on managing across the traditional functional areas of purchasing operation and physical distribution. They are material management, merchandising and logistics and supply chain management (SCM) (Cohen & Roussel, 2004; Blanchard, 2006; Daft, 2007).

During the last twenty years or even broader, more ambitious and strategically significant concept has emerged - SCM. SCM is a broader and a strategically more significant concept which includes the entire SC from the supply of raw material, through manufacture, assembly and distribution to the end customer.

The Role of Information Technology in Supply Chains

In last decade information technology has had significantly influence on business processes throughout the entire supply chain (Gunasekaran & Ngai, 2004; Manthou et al., 2004). A very simple definition of information technology utilized in supply chain defines it as a set of hardware and software that enable entities involved in the supply chain to collect and analyze data and information, that are foundation for their decisions (Chopra & Meindl, 2013, p. 500).

Organizations involved in supply chains use different information technology solutions that are aimed to support either internal processes in organizations or solutions that are designed to support collaboration between entities involved in the entire supply chain (Li et al., 2001; Gunasekaran & Ngai, 2004; Simchi-Levi et al., 2009, p. 407). In the frame of collaboration between the focal organization and other entities in the supply chain, information technology represents

an important support for managing supplier and customer relationships (Chopra & Meindl, 2013, p. 503). Using different information technology solutions, that support collaboration and especially exchange of information between all entities in the supply chain, represent an important success factor. Commonly used information technology solutions are enterprise resource planning, decision support systems, artificial intelligence, management information systems (Gunasekaran & Ngai, 2005; Simchi-Levi et al., 2009, p. 407).

From a view point of supply chain two most important milestones were the introduction of a computer hardware and software and in the mid-1990s internet (Sahin & Robinson, 2002; Murphy & Wood, 2004, p. 9; Chen et al., 2012). According to the different phases of supply chain development, we can conclude, that in first and second phase (i.e., materials management, merchandising, physical distribution) there had been a very basic support of information technology, due to its non-existence or very low level of information technology development in that time.

During the phase of supply chain consolidation (in 1980s) introduction of computers, importantly enhanced management of large amounts of data and information in organizations. Advancement in computer hardware, software and hardware's capacities have allowed single members of the supply chain to make faster, more informed, and more accurate decisions, required for their success (Murphy & Wood, 2004, p. 9). Computers were used for local work in frame of single organizations. In these circumstances, computers represents an important tool for management of the rapidly increasing amount of data and information.

In the phase of functional integration of the supply chain (in 1990s), where there was strong emphasis on linking different organizations (i.e. inter-organizational integration), the internet had played a crucial role in enabling a new way of collaboration between supply chain partners (Li et al., 2001; Christopher, 2011, p. 144). The early to mid-1990s witnessed a growing recognition that there could be value in coordination of the

various business functions not only within single organizations, but across organizations as well (Nigel, 1996; Rushton et al., 2001; Slack et al., 2006; Christopher, 2011). Functional integration was enabled and/or supported largely by the development of the internet, which makes connections and collaboration among geographically dispersed entities in supply chain possible. During the late 1980s and early 1990s, until the development of sophisticated information technology, information technology, especially computers and beginnings of the internet, importantly support collaboration among entities in the supply chain.

Today's, in the frame of supply chain management concept, supply chains are based on well developed information technology. Thus, computers, internet, and network infrastructure represent a backbone of the modern integrated supply chain (Rodrigue, 1998; Manthou et al., 2004; Wang & Chan, 2010). Information technology in today's supply chains, thus has become a prerequisite for success and represents a powerful tool for improving supply chain effectiveness and efficiency.

Usage of computers, coupled with the emergence of the internet and advancement in network equipment, has significantly changed the way of exchanging information and collaboration among entities in the supply chain in the last decade (Murphy & Wood, 2004, p. 41; Chopra & Meindl, 2013). Leading organizations very soon recognized that the key to successful supply chain is usage of different information technology solution that supports their work in frame of the supply chain (Manthou et al., 2004; Subramani, 2004; Christopher, 2011, p. 144).

In terms of supporting processes throughout the entire supply chain, we can find in practice of supply chain plethora of information technology solutions, which support supply chain management. Those solutions, for instance enable better management of customer relationship management and management of supplies, acquiring of knowledge in organizations, etc. (Simchi-Levi et al., 2009). On the other hand, there are also some new emerging solutions, which are based on in-

formation technology and importantly contribute to the enhancement of supply chain management activities, like collaborative innovations, corporate blogs, radio-frequency identification, and shared services centers (Pal & Kapur, 2009; Meidute et al., 2012; Dabic et al., 2013). For the selected emerging solutions in our focus, we provide following short definitions.

Shared service centers reduce costs, since one or several operations are consolidated into shared operation and used by multiple divisions, organizations, users. Based on information technology platforms, centralized services are available to all potential users (Rigby & Bilodeau, 2011). Radio frequency identification (RFID), enable wireless identification of objects and allows tracking the movement of the material flow within the supply chain (Meidute et al., 2012). Collaborative innovations enable innovation processes and generation of innovations in all areas, like product and service improvement, processes improvement, with the support of information technology platforms to easier gather ideas. An important part of collaborative innovation is an architecture for supporting the participation of organizational members in collaborative innovation processes. In that frame are often emphasized corporate blogs as a way in which organizational members participate in collaborative innovations (Gloor, 2006; Pal & Kapur, 2009; Nedelko & Potocan, 2013).

Information Technology Solutions for Supporting Supply Chain Management

In this section we will outline the actual state of management practices utilization that are used in supply chains in order to support supply chain management in selected worldwide areas. Among a plethora of used practices, we will focus on the solutions that are based on information technology. An overview of different management solutions utilization in selected areas is outlined in Table 1 (Potocan & Dabić, 2012; Dabic et al., 2013).

Above outlined results in table 1 reveals different patterns for top used management tools in different worldwide regions. The customer relationship management tool is among the top used in well developed areas of North America and Europe, as well as organizations in Asia-Pacific region. Turning to the catching up economies like Slovenia and economies in Latin America, it is evident that in these economies are in the forefront other tools, whereas for instance customer relationship management is placed at sixth place in Slovenia.

Differences in patterns of customer relationship management use worldwide can be attributed to the different levels of the country's development and especially specific characteristics of organizations operating within different economic and cultural settings. Thus, well developed economies have already recognized the importance of managing and especially maintaining good relationships with their customers (Kumar, 2010). On the other hand, organizations in catching up economies have also recognized the importance of good relationships with their customers, but they are still preoccupied with issues related to the optimization of their business, like outsourcing activities, looking for core competencies, managing and capturing knowledge, implementation of total quality concepts, etc. (Potočan & Mulej, 2007; Potocan et al., 2012; Dabic et al., 2013).

DISCUSSION AND PRACTICAL IMPLICATIONS

With the emergence of information technology, especially the internet, there has been a rapid increase in terms of exchanging information between entities in the supply chain based on different information technology solutions. Thus, current supply chain management solutions, which are based on modern information technology and adjacent network equipment, enable seamless exchange information across organizational borders,

Table 1. Management solutions usage in selected worldwide areas^a

Management Tool	Use of Management Tools - Rank							
	Global 2006	Global* 2008	North America	EU 15	Asia-Pacific	Latin America	Croatia	Slovenia
Strategic Planning	1	2	1	1	2	1	8	8

^aNote: Data for Global average (GL) 2006 and 2008, North America (NA) 2006, European Union 15 (EU) 2006, Asia Pacific (AP) 2006, and Latin America (LA) 2006 are calculated upon results from management practices utilization research (Rigby & Bilodeau, 2009; Rigby, 2011). Data for Slovenia and Croatia are adopted from research of management practices in Central and East Europe economies (Potocan et al., 2012; Dabic et al., 2013) Abbreviation t stands for tight result. (-) Stand for not applicable.

between entities in the supply chain (Rodrigue, 1998; Chopra & Meindl, 2013).

According to outline cognitions, it is evident that plethora of management solutions supports supply chain management in practice. Among those several solutions are based on information technology. Among those solutions, that are based on information technology, we can emphasize some solutions as emerging, due to their novelty

and low level of utilization for supporting supply chain management. Based on above outlined cognitions, we will focus on several emerging solutions, out of 25 top used, like collaborative innovating, corporate blogs, radio-frequency identification, and shared services centers. Throughout discussion, we will outline potential and possible barriers of several emerging solutions, for supporting supply chain management.

The main advantage of collaborative innovations is to support innovative processes and generation of ideas, suggestions, and potential innovations and innovations for enhancing products, services, processes, leadership style, organizational methods, etc. With the help of information technology, plethora of ideas can be generated, filtered and reused again in getting the most innovative ideas. Organizational members don't have to be collocated; rather they can participate via corporate blogs, as a mean for enabling the participation. A possible drawback can be related to the huge amount of gathered ideas and needed time for filtration of the ideas and further development of these ideas. Another possible drawback it related to the ethical issues, regarding ownership of the ideas developed and possible free-riding of participants.

The key features of RFID utilization in supply chains are related to the reduction of needed time to handle and identification of goods arriving or leaving in the organization. Another key benefit of using RFID is high speed of identification and tracking of the objects. Utilization of RFID among partners in supply chain enables to scan and record all goods by all members in the supply chain using the same platform and/or approach. With such approach, supply chain members can overcome problems with time consuming identification of goods arriving and leaving organizations as well as problems with different systems for identification of goods (e.g. different bar codes, incompatible systems). The main drawback is associated with the costs of labeling and standardizing products and/or goods identification tags in order to ensure compatibility between all members of the supply chain. In order to implement RFID throughout the entire supply chain, members also need to have appropriate equipment to generate, read and modify RFID identifications.

Shared service centers contribute to the reduction of costs and can speed up the processes in supply chains, by, for instance centralizing and especially standardizing the process or several processes. For instance shared service centers are

successfully used and organizations send positive feedback about its utilization. Commonly are used in the areas of finance and customer services and customer support. An important feature of shared service centers is that entities involved in the supply chain can establish shared service centers, which enable support for all members.

With the implementation of shared service centers entities in the supply chain will have a common platform, which will enable easier collaboration between entities in the supply chain and will diminish the impact of barriers of possible technology incompatibles. Thus, all suppliers will have a common platform for communication with focal company and especially for managing orders. Currently, in business practices companies often encounter problems of incompatibility of information platforms for managing supplies and orders. Suppliers often need interfaces, which increases costs and require plenty of work with suppliers. A special case is also small supplier, which do not have large sums of money to invest in expensive enterprise resource planning systems, that will be compatible with larger of the focal company.

Thus establishing of a common platform by focal company will resolve these problems of expensive software with smaller suppliers as well the processes will be standardized and simplified for employees in focal company, since all suppliers will have the same interface and common platform for ordering. Even more convenient is utilization of such approach in case of vendor managed inventory systems, with which suppliers manage inventories of focal company.

A drawback can be related to the process of standardizing this service for all entities in the supply chain. Another consideration can be related to the suppliers or distributions, which are part of several supply chains. In such cases, they will need to have their own system for instance for keeping records, while they will face differing platforms when collaborating with different supply chains.

Slovenia is a small economy, which is importantly dependent upon export, thus many organizations are members of different supply chains or

networks across the globe, especially in Europe. Thus, low level of supply chain management information technology solutions utilization in Slovenian organizations, importantly hinders the flow of information exchange between partners in the supply chain. In that framework, some Slovenian organizations complain that they have troubles to enter into “larger supply chains” that intensively use supply chain management solutions, like automated data exchange, vendor managed inventory, etc., for collaboration with their partners. Reason lies in the fact, that members and/or focal organization in supply chain does not practice anymore “the old model of collaboration between supply chain partners”, like an electronic exchange of order via email, using faxes, email, etc.

In that frame, emerging solutions represent an important consideration for suppliers in the larger supply chain. Again, despite huge potential of emerging solutions for enhancing and optimizing supply chain management, there is still a plethora of open issues for smaller players in supply chains. Most important hindering factor is associated with adoption of “rules of focal company”. This problem magnifies when an organization is a member of several supply chains. For instance, like having different platforms for managing of supplies, different requirements in frame of RFID utilization, etc.

In terms of limitations, most significant are: (1) considering the limited number of management tools, (2) focus only on several emerging management solutions, and (3) discussing the role of information technology in supply chain management, only through the lenses of several selected emerging management solutions, based on information technology.

FUTURE RESEARCH DIRECTIONS

Building on the limitations the main directions of future research are: (1) including higher number of management tools in analysis, to more comprehensively evaluate usage of tools that are

supported with information and communication technology, (2) examine also other potential tools, which are based on information technology and could enhance supply chain management, and (3) discussing the role of information technology in supply chain management, by taking into consideration also key management tools used in supply chain in order to obtain more comprehensive picture about emerging solutions.

CONCLUSION

This chapter outlines the potentials of emerging information technology solutions to support and optimize supply chain management in practices. In that framework are recognized main potential of several selected emerging management solutions, like collaborative innovations, corporate blogs, radio-frequency identification, and shared services centers. Analysis of potentials and drawbacks reveal that in the long run those solutions will become standardized solutions in backing up supply chain management activities. It is also evident that joint actions of focal company as well as other participants in the supply chain will be needed in order to yield all possible benefits. For instance, organizations acting as suppliers can strive towards for common platforms for managing supplies in order to diminish problems, but focal company must provide adequate support - i.e. provide common platform and all necessary steps. On the other hand, the situation is, inversely, when for instance focal company want to introduce RFID. In such case supplier needs to adapt to the requirements of focal company.

KEY TERMS AND DEFINITIONS

Collaborative Innovations: Enable innovation processes and generation of innovations in all areas, like product and service improvement, processes improvement, with the support of information technology platforms to easier gather ideas.

Customer Relationship Management Solution: Is an information technology supported tool, which enables organizations to collect and manage large amounts of data about customers.

Corporate Blogs: Are defined as a way in which organizational members participate in collaborative actions, like collaborative innovations.

Emerging Solutions: Is an information technology supported tool, which support information exchange, collaboration and processes in supply chains. Typically, these solutions are novel and less used in business practice. Most commonly emphasized emerging solutions are collaborative innovating, corporate blogs, radio-frequency identification, and shared services centers.

Information Technology Solutions: Are different types or applications of information technology that support processes in organizations. In terms of supply chain, information technology solutions are aimed to support customer and supplier relations, as well as internal processes in single organizations involved in the supply chain.

Supply Chain Management Solution: Is an information technology supported tool, which enables synchronization of the efforts of all parties involved in supply chain, from suppliers, through manufacturers, distributors, dealers, to end customers.

Radio-Frequency Identification: Enables wireless identification of objects and allows tracking the movement of the material flow within the supply chain.

Shared Services Centers: Reduce costs, since one or several operations are consolidated into shared operation and used by multiple divisions, organizations, users, etc.

Samsung Company and an Analysis of Supplier–Side Supply Chain Management and IT Applications

Robert Morris University, USA

INTRODUCTION

Supply Chain Management

Supply chain management (SCM) is the oversight of materials, information, and finances as they move in a process from supplier to manufacturer to wholesaler to retailer to consumer. SCM involves coordinating and integrating these flows both within and among companies. It is said that the ultimate goal of any effective SCM-related system is to reduce inventory (with the assumption that products are available when needed). As a solution for successful SCM, sophisticated software systems with web-based interfaces are competing with web-based application service providers (ASP) who promise to provide part or all of the SCM service for companies who rent their service (Von Haartman, 2012).

The discipline of SCM includes the active management of a company's supply chain activities to maximize customer value and achieve a sustainable competitive advantage. It represents a conscious effort by the supply chain firms to develop and run supply chains in the most effective & efficient ways possible. Supply chain activities cover everything from product development, sourcing, production, and logistics, as well as the information systems needed to coordinate these activities (Pradhananga, Hanaoka, & Satayaprasert, 2011).

The organizations that make up the supply chain are linked together through physical flows and information flows. Physical flows involve the transformation, movement, and storage of goods and materials (Idris, Rahman, Hassan, Aminudin, & Alolayyan, 2013; Ketikidis, Hayes, Lazuras, Gunasekaran, & Koh, 2013; Mateen & More, 2013; Varaprasad, Sridharan, & Unnithan, (2013). They are the most visible piece of the supply chain. But just as important are information flows. Information flows allow the various supply chain partners to coordinate their long-term plans, and to control the day-to-day flow of goods and material up and down the supply chain. SCM flows can be divided into the product flow, the information flow, and the finances flow (Basu & Nair, 2012; Brito & Botter, 2012; Bulcsu, 2011). The product flow includes the movement of goods from a supplier to a customer, as well as any customer returns or service needs. The information flow involves transmitting orders and updating the status of delivery. The financial flow consists of credit terms, payment schedules, and consignment and title ownership arrangements.

SCM Basics

There are basic components that make up SCM: plan, source, make, deliver, and return (Sprovieri, 2008; Smith, 2011; Summers & Scherpereel, 2008). Planning is the strategic portion of SCM,

as companies need a strategy for managing all the resources that go toward meeting customer demand for their product or service. A big major portion SCM planning is developing a set of metrics to monitor the supply chain so that it is efficient, costs less and delivers high quality and value to customers. Next follows source where companies must choose suppliers to deliver the goods and services they need to create their product. Therefore, supply chain managers must develop a set of pricing, delivery and payment processes with suppliers and create metrics for monitoring and improving the relationships. And then, SCM managers can put together processes for managing their goods and services inventory, including receiving and verifying shipments, transferring them to the manufacturing facilities and authorizing supplier payments.

Making is the manufacturing step. Supply chain managers schedule the activities necessary for production, testing, packaging and preparation for delivery (Tari & Sabater, 2004; Tiwari, Turner, & Sackett, 2007; Varaprasad, et al., 2013). This is the most metric-intensive portion of the supply chain, where companies are able to measure quality levels, production output and worker productivity. Delivering is the part that many SCM insiders refer to as logistics, where companies coordinate the receipt of orders from customers, develop a network of warehouses, pick carriers to get products to customers and set up an invoicing system to receive payments. Returning can be a problematic part of the supply chain for many companies. Supply chain planners have to create a responsive and flexible network for receiving defective and excess products back from their customers and supporting customers who have problems with delivered products.

There are several types of types of SCM software that deals with planning applications and execution applications (Sodhi & Lee, 2007). Planning applications use advanced algorithms to determine the best way to fill an order. Execution applications track the physical status of goods, the management of materials, and financial informa-

tion involving all parties. Some SCM applications are based on open data models that support the sharing of data both inside and outside the enterprise (e.g., this is called the extended enterprise, and includes key suppliers, manufacturers, and end customers of a specific company). This shared data may reside in diverse database systems, or data warehouses, at several different sites and companies.

By sharing this data upstream (e.g., with a company's suppliers) and downstream (e.g., with a company's clients), SCM applications have the potential to improve the time-to-market of products, reduce costs, and allow all parties in the supply chain to better manage current resources and plan for future needs. Increasing numbers of companies are turning to websites and web-based applications as part of the SCM solution (Paksoy & Cavlak, 2011; Pettersson & Segerstedt, 2011). A number of major websites offer procurement marketplaces where manufacturers can trade and even make auction bids with suppliers.

BACKGROUND

Case Study: Samsung Electronics Company

Background and History

Samsung Electronics Co., Ltd. is a world leader in digital media and digital convergence technologies industries. Samsung operates in over 50 countries worldwide with its main headquarters being located in city of Suwon, South Korea. President of Samsung Group is Mr Lee Kun-Hee who has held the role since the passing of his father who founded Samsung, Lee Byung-Chul. Samsung's name can be broken down into "sam" meaning three and "sung" meaning star in Korean." Samsung Electronics Co., Ltd. is mainly engaged in the production of consumer electronic products. It operates in three business divisions: consumer electronics (CE) division, which involves in the

color televisions (CTVs), monitors, printers, air conditioners, refrigerators, laundry machines and others; information technology & mobile communications (IM) division, which involves in the production of computers, handheld phones (HHPs), network systems, digital cameras and others, as well as device solutions (DM) division, which is divided into semiconductor and display business parts, providing dynamic random access memories (DRAMs), flashes, thin film transistor-liquid crystal displays (TFT-LCDs) and others. The Company distributes its products within domestic market and to overseas markets (Sodhi & Lee, 2007). Much of Samsung Electronics Company's manufacturing has since moved outside of Korea into emerging countries such as China and other countries in ASEAN such as Vietnam, the Philippines, and India. Some of the reasons for this transfer of labor overseas are to capitalize on the low cost as well as the raw materials available there.

Samsung Electronics was created in 1969 as a division of the mammoth Korean chaebol Samsung Group. The unit was established as a means of getting Samsung into the burgeoning television and consumer electronics industry. The division's first product was a small and simple black-and-white television that it began selling in the early 1970s. From that product, Samsung Electronics gradually developed a diverse line of consumer electronics that it first sold domestically, and later began exporting. The company also began branching out into color televisions, and later into a variety of consumer electronics and appliances. By the 1980s, Samsung was manufacturing, shipping, and selling a wide range of appliances and electronic products throughout the world.

During the 1970s and 1980s, Samsung Group created a number of electronics-related divisions, several of which were later grouped into a single entity known as Samsung Electronics Co., Ltd. Samsung Electron Devices Co. manufactured picture tubes, display monitors, and related parts. Samsung Electro-Mechanics Co. made VHF and UHF tuners, condensers, speakers, and other gear. Samsung Corning Co. produced television glass

bulbs, computer displays, and other components. Finally, Samsung Semiconductor & Telecommunications Co. represented Samsung in the high-tech microchip industry. Rapid growth in those industries, combined with savvy management, allowed the combined Samsung Electronics Co., Ltd., to become Samsung Group's chief subsidiary by the end of the 1980s (Sodhi & Lee, 2007).

Between 1977 and 1987, Samsung Group's annual revenues surged from US\$1.3 billion to US\$24 billion (e.g., about 20% of South Korea's entire GNP). Much of that growth was attributable to Samsung Electronics. Samsung's rapid rise and technical achievements put the company in the spotlight in the semiconductor industry. Its 4-megabit chip, in fact, had made it the leading global producer of DRAM chips by early 1995. Furthermore, Samsung was increasing its investment in development still further, as evidenced by a US\$2.5 billion outlay to develop a 64-megabit DRAM chip by 1998. In December of 1995, development on the world's first 1-gigabit synchronous DRAM chip was also in the works. Exports for the year increased to more than US\$10 billion.

Samsung's positive results continued in 2000 as the firm secured US\$26 billion in sales and US\$4.7 billion in net profits. Memory chips accounted for 38% of sales, information and telecommunications equipment secured 22%, digital media took 27%, and home appliances accounted for 8% of sales. The company looked to strategic partnerships, research and development, and growth, to maintain its positive financial record. In March 2001, it teamed up with Dell Computer Corporation in a US\$16 billion technology and research and development agreement. In addition, the company was selected by China to provide CDMA cellular phone networks in its four major cities.

Sales figures did decrease slightly in the first part of 2001, however, due to a slowdown in the personal computer market, an oversupply of LCDs, and a slowdown in the cellular market. Nevertheless, Samsung management continued to focus on remaining a leader in the electronics industry.

Samsung has made many innovations over the years in the electronics space often being the first one to do so. Some of these innovations include the following:

- Developed world's first 128MB Synchronous DRAM and 128MB Flash memory.
- Developed the world's first 64Mb DRAM, 256 Mb DRAM, and 1Gb DRAM.
- Developed the world's first 60-nano 8GB NAND memory chip.
- Developed the worlds' first 50nm 1G DRAM.
- Developed the world's first 30nm-class 64Gb NAND Flash™ memory.
- Developed the world's first 2Gb 50 NANO ("Fortune Global Top Company ...," 2016).

Mission and Strategy

Samsung's corporate mission statement and business philosophy: To fuel Samsung's aspirations to create new technologies that inspire the world, Samsung boldly invests billions in R&D and future technologies. Samsung operates 34 R&D centers globally, with 69,000 employees devoted to R&D. In 2013, Samsung invested USD 13.6 billion (KRW 14.3 trillion) in R&D and registered 4,676 new patents in the U.S. alone, ranking Samsung Electronics as the second-highest patent winner in the U.S. for the eighth consecutive year. Samsung's intellectual property portfolio today includes more than 100,000 patents ("Fortune Global Top Company ...," 2016).

Recognizing that great consumer experiences require a thoughtful integration of both hardware and software, Samsung Electronics has increased global investment to fuel software innovation, including embracing creative talent from both inside and outside the company. Samsung also strives to bring greater value to consumers' lives through its "Make It Meaningful" design philosophy, and today it employs some 1,500 designers across our global design centers in six countries.

The employees of Samsung Electronics are passionate about creating a better future for people and bringing about positive change in the communities in which we operate. Through Samsung Hope for Children programs, Samsung continues to pursue the goal of providing improved health, education and training opportunities to people around the world. Samsung also places a high priority on environmental sustainability, and, through their PlanetFirst™ initiative, Samsung are applying an innovative technology to achieve eco-friendly development throughout the product life cycle and to reduce our environmental footprint.

Samsung's plan for the future is driven by a deep understanding of people, cultures, and the impact of technologies that drive growth and create markets. To foster future growth, Samsung Electronics is pushing toward a 2020 corporate vision to "Inspire the World, Create the Future," and achieve annual revenue of USD 400 billion while cementing its reputation as one of the world's most innovative and admired companies ("Fortune Global Top Company ...," 2016).

SCM Approach

Since the electronics market changes quickly, Samsung need to be able to create a flexible production plan. The Samsung Group of companies have large, complex, global supply chains in most of the products it manufactures and makes extensive use of SCM solutions and process innovations to support and improve its operations. Most notably, at Samsung, advanced planning and scheduling (APS) systems have been adopted since the 1990s and have brought the company many successes in terms of operational excellence (Khanna, Song, & Lee, 2011). APS is especially well-suited to environments where simpler planning methods cannot adequately address complex trade-offs between competing priorities. Production scheduling is intrinsically very difficult due to the (approximately) factorial dependence of the size of the solution space on the number of items/products to be manufactured. APS systems

function as resources for efficient planning and scheduling. This type of system tracks costs based on the activities that are responsible for driving costs in the production of manufactured goods. It also allocates raw materials and production capacity optimally to balance demand and plant capacity. APS systems utilize where plant capacity is constrained, many different products are produced in each facility, or when products require a large number of components. To achieve the economy of scale, Samsung standardize processes and parts and the majority of components are produced in Korea.

Despite the extensive use of SCM solutions and process innovation to improve global business operation, in 2004, the company still felt that its supply chain operations had significant room for improvement. In the early 1990s, the Group's senior management decided to capitalize on the potential synergy between SCM and six-sigma metrics (Yang, Choi, Park, Suh, & Chae, 2007). Six-sigma is a set of techniques and tools for process improvement (Idris, et al., 2013; Ketikidis, et al., 2013; Park & Min, 2013; Rajapakshe, Dawande, & Sriskandarajah, 2013; Rajeev, Rajagopal, & Mercado, 2013). Six-Sigma is a disciplined, data-driven approach and methodology for eliminating defects (e.g. driving toward six standard deviations between the mean and the nearest specification limit) in any process – from manufacturing to transactional and from product to service. Samsung's SCM Business Team (SBT) researched six-sigma approaches at General Electric (GE), DuPont and Honeywell to get perspectives on how other companies have innovatively applied six-sigma to similar needs. Later, they create the methodology based on GE approach called DMAEV (e.g., define, measure, analyze, enable and verify).

Samsung was ranked 7th in a respected analyst's ranking of the global top 25 companies in supply chain excellence (Yang, et al., 2007). There are various approaches and systems available for process innovation. Six sigma and SCM-based metrics are among those techniques aiming for

process and quality improvement, and synchronization of a company's value chain, from inbound logistics to sales and customer services (Carvalho, Cruz-Machado, & Tavares, 2012; Hamidi, Farahmand, Sajjadi, & Nygard, 2012; Kumar, Shankar, & Yadav, 2011; Mathirajan, Manoj, & Ramachandran, 2011; More & Babu, 2012). At Samsung, SCM and six-sigma have been two important enablers for the group's management innovation and growth.

However, management realized that there is significant room for improvement in its SCM operation. Thus, the effort has been synthesizing SCM and six-sigma and developing a unique six-sigma based methodology to improve its SCM operation. Samsung's effort and investment has turned out to be fruitful. Their SCM six-sigma program has produced highly qualified and talented SCM specialists, who are currently training the methodology to other members in their organizations and leading SCM projects. SCM projects are being prepared and conducted in a more disciplined way and their outcomes are continuously monitored and shared through Samsung's repository for six-sigma. The company's endeavor for global optimum is continuing and SCM and six-sigma metrics are expected to play an increasingly enabling role.

Samsung also have implemented short cycle time and low inventory (SLIM) methodology in its electronics manufacturing processes. SLIM is a set of methodologies and scheduling applications for managing cycle time in semiconductor manufacturing. SLIM includes methodology for calculating target cycle times and target WIP levels for individual manufacturing steps, heuristic algorithms for factory floor scheduling, and optimization-based capacity analysis (Leachman, Kang, & Lin, 2002). Between 1996 and 1999, Samsung Electronics Corp., Ltd., implemented SLIM in its semiconductor manufacturing facilities (Leachman, et al., 2002). It reduced manufacturing cycle times to fabricate dynamic random access memory devices from more than 80 days to less than 30. Considering the decline of sell-

ing prices for dynamic random access memory devices, SLIM enabled Samsung to capture an additional US\$1 billion in sales revenue compared to the revenue it would have realized had cycle times not been reduced (Leachman, et al., 2002).

Samsung MIS Applications

In the current ever-developing business world, Samsung has employed various information technology (IT) applications in order to better manage its supply chain. Perhaps, the initial challenge was to develop a model for managing the supply chain that addressed Samsung's specific business requirements. The company relied heavily on existing technology while working internally to develop its own custom application set based on the observations of successful systems. The result is a SCM system with end-to-end visibility into every segment of the supply chain. Samsung annually manages over 50,000 employees across 42 global research facilities as well as a global network of 286,000 employees in more than 80 countries. Because it currently contains no brick and mortar locations getting the products from the manufacturing factory to the retail shelf is the biggest concern of Samsung's which can be a daunting task with so many employees and locations needing to coordinate seamlessly. In order to manage such a vast amount of goods, Samsung implemented wireless local area network (LAN), radio-frequency identification (RFID), and developed custom applications for internally managing the data.

Wireless LAN

Wireless local area network or (WLAN) is a communications network that provides connectivity to wireless devices within a limited geographic area. Wi-Fi is the universal standard for wireless networks. In the office, Wi-Fi networks are adjuncts to the wired networks. At home, a Wi-Fi

network can serve as the only network since all laptops and many printers come with Wi-Fi built in, and Wi-Fi can be added to desktop computers via USB. Wi-Fi is achieved with a wireless base station, called access points. Its antennas transmit and receive a radio frequency within a range of 30-150 ft. through walls and other non-metal barriers. Since all wireless and wired computers are interconnected, they can exchange data with each other for backup and file sharing.

An enterprise-class WLAN employs a large number of individual access points to broadcast the signal to a wide area. The access points have more features than home or small office WLAN equipment, such as better security, authentication, remote management, and tools to help integrate with existing networks. These access points have a larger coverage area than home or small office equipment, and are designed to work together to cover a much larger area. This equipment can adhere to the 802.11a, b, g, or n standard, or to security-refining standards, such as 802.1x and WPA2.

True efficient business environments depend on a reliable and fast network to meet the rising demand for bandwidth. In order to support enterprise mobility trends like BYOD, the Internet of Things (IoT) and digital consumption, Samsung's WLAN solution provides an improved end-user experience with noticeably faster network connectivity. Higher network speeds allow users to get on and off the network quickly, which conserves batteries and maximizes airtime for all devices ("Samsung Smart LAN," 2015).

Unlike many competitors, Samsung's WLAN technology is designed to function similarly to its own LTE solutions, fairly and efficiently optimizing the distribution of airtime, which leads to higher throughput, capacity, and an overall improved experience. Additionally, Samsung Wireless LAN simplifies network administration for IT managers, allowing for faster and more effective device management and service ("Samsung Smart LAN," 2015).

RFID Applications

RFID tags are part of intelligent automatic identification and data capture technologies (AIDC) that can communicate to a networked system to track every product that you put in a customer's shopping cart. RFID tags, a technology once limited to tracking cattle, are tracking consumer products worldwide. Many manufacturers use the tags to track the location of each product they make from the time it's made until it is pulled off the shelf and tossed in a shopping cart (Tari & Sabater, 2004; Tiwari, et al., 2007; Varaprasad, et al., 2013). RFID tags are an improvement over bar codes because the tags have read and write capabilities. Data stored on RFID tags can be changed, updated and locked. Some stores that have begun using RFID tags have found that the technology offers a better way to track merchandise for stocking and marketing purposes. Through RFID tags, stores can see how quickly the products leave the shelves and which shoppers are buying them.

Samsung have joined with DHL and Media-market to pilot an RFID-enabled smart packaging concept designed to improve supply chain efficiency for high-value electronics goods in Europe (Johnson, 2013). The supply chain for consumer electronics products like TVs, digital cameras, video games and mobile phones is very complex. Often the flow of merchandise comes from multiple sources including manufacturers and assemblers. Goods are then passed off to logistics providers for packaging, transport and delivery to warehouses of retail venues, where they are then encoded before being displayed on store shelves. Adding to the supply chain complexity is the wide variety of very valuable items shipped, many with very small dimensions. These characteristics make electronic products much more susceptible to potential vulnerabilities throughout the supply chain such as theft and loss.

RFID traceability begins when DHL receives products from Samsung at two warehouse locations that serve as high-value storage areas. In these restricted areas, products are inspected, wrapped

and stocked. Larger products like televisions are stocked in a traditional bulk area. RFID tags are activated by connecting the tag's serial number to the product's serial number. From thermo-retraction, to stockpiling, picking and shipment preparation, the tags enable the electronics products to be monitored at each step (Johnson, 2013).

The pallets pass through a door that is equipped with a scanner and RFID antennae that monitor the exit of goods from the high-value storage area which can read up to 300 tags per pallet (Johnson, 2013). The operator verifies the exiting process from the storage area through a monitor that reports the quantity and the relative shipment. After it leaves the storage area, the pallet is placed on the exit platform with its untagged counterparts. Each product is traced and identified from the picking process, to the loading phase onto the vehicle and to the Saturn retail venue.

Upon arrival at the retail venue, the shipment passes through a gateway equipped with scanner and RFID antennae that automatically monitors the incoming merchandise. RFID also allows Samsung to reduce stock in transit and to have better visibility into sell out information. In addition, products arrive at the retail venue more quickly and make it to the store shelves faster, a crucial element for electronics retailers and manufacturers that battle product obsolescence. RFID-tagged products enable the possibility to reduce self-service product stock out and the possibility of obsolescence, a very relevant occurrence as far as notebooks are concerned. RFID has also allowed the retailers to free up employees from inventory tasks and be put to use making sales.

IT Applications

MySingle™ is an intranet service created in house by Samsung in order for employees to communicate worldwide. An intranet is a network based on TCP/IP protocols belonging to an organization, usually a corporation, accessible only by the organization's members, employees, or others with authorization. An intranet's websites and

operations look and act just like any other Web sites, but the firewall surrounding an intranet fends off unauthorized access. Like the Internet itself, intranets are used to share information. Secure intranets are now the fastest-growing segment of the Internet because they are much less expensive to build and manage than private networks based on proprietary protocols.

Samsung's intranet was created by their subsidiary SDS. Samsung SDS provides information technology services which include consulting services, technical services, and outsourcing services. SDS is expanding its business area by investing on R&D and emerging IT technologies such as U-city, RFID and Engineering Outsourcing. SDS provides its IT services by operating 11 offices and data centers in 11 countries.

The e-mail system is a web-client first devised in 2000 by Samsung subsidiary Samsung Data Systems and went live across the company's entire network in 2001. The previous system was not that effective in communicating with each other. It is reported that a total of 425,000 employees of Samsung make 486 searches for employee information such as telephone numbers and e-mail addresses a day on average, which takes considerable time since the system has required many clicks and an exact name to find information on other employees.

Samsung, therefore, has enhanced the effectiveness of the intranet system. Aside from a name, searching the name of position or team can enable the person they are looking for to be located. The system is also set up to work with foreign based employees as well. Before, they used to be required to type in an exact full name of a Korean worker which is quite hard for them to do. Now with the renewed system, employees worldwide search for a person they want to communicate with without typing in their full name.

"Provided that it takes 20 seconds for a staff member to search for another member, it would 27,000 hours, to search for 486 employees," said Yoon-Jung (Personal Note 1, 2015), Samsung Portal UX Team Leader. "Thanks to the renewed

system, the speed is growing much faster than before, which makes workers much more satisfied by the progress," she added. In 2016, the leading Korean company plans to expand the streamlined system into other systems such as mail receiver search, document approver search and business card search. The system will also be morphed into a Microsoft-based platform as Samsung looks to reinforce real-time communications with 400,000 Samsung employees worldwide and to enhance their business performance by sophisticating its intranet system. Samsung Group will pilot-run an MS-based work system and will decide when to apply the system across the board based on the outcome of the pilot run. Yoon-Jung (Personal Note 1, 2015) from Samsung Group said, "There were issues with having effective and smooth communication with overseas employees under old system. So by creating everything on one platform and integrating everyone we hope to create better cohesion and unity among Samsung employees."

Managerial Application of IT Technologies to SCM

To optimize the functionality of their supply chain, Samsung has implemented existing technologies as well as providing customized tools for greater visibility throughout the supply chain. The development and combination of these technologies, while difficult in the beginning, have accounted for value added to the business. With the vast amount of manufactured goods that need to be transported daily across vast distances, Samsung has employed several systems to assist in accurately managing data collection. Two noteworthy technologies include wireless local area network (LAN) and RFID-embedded technologies.

The wireless LAN (WLAN) allows for information sharing within a given area. The system is hampered by its limited range along with the need to be within the specified region in order for this system to work efficiently and effectively. Because of the expanding technology and innovations to come, the company is poised to not only utilize

but provide the tools for other enterprises who wish to use WLAN in their SCM systems. By providing the WLAN and devices that operate on the network, Samsung is able to streamline their products to create an efficiency that can lead to a competitive advantage.

FUTURE RESEARCH DIRECTIONS

In addition to using wireless LANs, Samsung is piloting programs which use RFID-embedded technologies to further enhance its inventory controls. Currently with other systems barcodes are specifically adapted for a certain distribution center and are not universally recognized throughout the organization. The use of RFID is still in its infancy with Samsung, but the consensus is that eventually, if implemented accordingly the RFID could universalize the management of inventory. RFID-tagged products enable the possibility to reduce self-service product stock out and the possibility of obsolescence, a very relevant occurrence as far as notebooks are concerned. RFID has also allowed the retailers to free up employees from inventory tasks and be put to use making sales.

MySingle™ is simply an intranet knowledge center which allows each employee the ability to submit anything they deem useful to any aspect of the business. From a supply chain stance, it provides employees at any point along the supply chain access to vital information and if necessary, to join forces with other employees on work projects. The payoff is that employees who are greater informed generally make better decisions, this further adds value to the business.

CONCLUSION

As the emphasis on six-sigma quality, SCM metrics, and IT-technologies continues to grow as companies place more emphasis on cost effective logistics, Samsung is well placed to adapt to changing needs and or tastes of its customers

more rapidly. By utilizing available technologies Samsung has continued to foster positive change internally. Samsung has seen its brand grow to be famous globally for its service and design, its commitment of its employees, and reliable product innovations.

Many companies look to Samsung for their own SCM systems and IT applications for inspiration and assistance in their own enterprises. Samsung takes on a responsible approach to enterprise and global citizenship as well as pioneering globalization with its many partners and customers. Management at the company is willing to take their company in the global economy in a progressive direction for the next generation. Ultimately, the acquisition and execution best business practices and processes previously mentioned are done for the purpose of achieving the company mission of creating superior products and services that contribute to a global society.

KEY TERMS AND DEFINITIONS

Automatic Identification and Data Capture Technologies (AIDC): Types of AIDC-related technologies to leave the human element out of the data collection and storage functions of information derived from manufacturing, integrated through the manufacturing process, type of authentication concerns, and/or e-security strategies, and relationship links to customer profiles. Typical types of AIDC include, bar-coding, RFID, magnetic strips, touch memory, and smart cards.

Internet of Things (IoT): IoT is a term that is applied to the general network of physical connected objects (e.g., services, vehicles, buildings and other items) that have mutually connected and enabled hardware, software, sensors, and network connectivity that allows communication and sharing of data and its protocols.

Operations Efficiency: Improving efficiency and reducing waste is a major challenge for hospitals and other patient care facilities looking to lower the cost of providing healthcare services. Far and away the largest contributor to operational costs in this industry is patient care activities. Since most clinical decisions involve managing products and medical supplies, finding ways to more efficiently manage supply chain activities can have a big impact on overall operational performance.

RFID-Embedded Technologies: RFID technologies are types of automatic data capture techniques that use a combination of active and passive senders and receivers to collect and store codified information for further uses. The implementation of such technologies should lead to improved managerial and/or supply chain performance. On the surface, there appears to be few drawbacks to implementing such technology into a production process, assuming it enhances performance and improves output of the product. The main issues surrounding the RFID applications are whether the initial costs and labor required to utilize this technology are worth it, and will result in a positive outcome of revenues.

Short Cycle Time and Low Inventory (SLIM) Methodology: In its electronics manufacturing processes, SLIM is a set of methodologies and scheduling applications for managing cycle time in semiconductor manufacturing. SLIM includes methodology for calculating target cycle times and target WIP levels for individual manufacturing steps, heuristic algorithms for factory floor scheduling, and optimization-based capacity analysis.

Supply Chain Management/Performance: In basic terms, supply chain is the system of organizations, people, activities, information and resources involved in moving a product or service

from supplier to customer. The configuration and management of supply chain operations is a key way companies obtain and maintain a competitive advantage. The typical manufacturing supply chain begins with raw material suppliers, or inputs. The next link in the chain is the manufacturing, or transformation step; followed the distribution, or localization step. Finally, the finished product or service is purchased by customers as outputs. Service and Manufacturing managers need to know the impact of supply on their organization's purchasing and logistics processes. However, supply chain performance and its metrics are difficult to develop and actually measure.

Simulating Complex Supply Chain Relationships Using Copulas

Krishnamurty Muralidhar

University of Oklahoma, USA

Rathindra Sarathy

Oklahoma State University, USA

INTRODUCTION

Supply chains involve complex interactions between different aspects of the research question and it is extremely difficult (if not impossible) to derive closed-form analytical solutions, leaving simulation as the only available alternative. The use of simulation in functional areas of business is well documented and includes accounting, finance, marketing, and other areas (Pegden et al., 1995). The analysis of supply chain systems is no exception. Recently, Waller and Fawcett (2012) observed that "...as simulation methods and technology are advanced, metaheuristics exist to find near optimal solutions, and powerful optimization is now in the hands of nearly any manager, let us not just model these simple systems, let us model the realistic, complex systems—in for a penny, in for a pound." The statement "When all else fails, there is simulation!" (Evers and Wan, 2012) is by no means an exaggeration.

The Council of Supply Chain Management Professionals defines supply chain management as encompassing "the planning and management of all activities involved in sourcing and procurement, conversion, and all logistics management activities. Importantly, it also includes coordination and collaboration with channel partners, which can be suppliers, intermediaries, third-party service providers, and customers. In essence, supply chain management integrates supply and demand management within and across companies." When modeling this complex system, simulation may be

the best alternative as the analytical tool (Waller and Fawcett, 2012). Swaminathan et al. (1998) also strongly argue for the use of simulation in supply chains.

This is because complex interactions between different entities and the multitiered structure of supply chains make it difficult to utilize closed-form analytical solutions. Benchmarking solutions provide insights into current trends but are not prescriptive. This leaves simulation as the only viable platform for detailed analysis for alternative solutions. Evers and Wan (2012) offer an excellent analogy in support of simulation. Griffis et al (2012), Rogers et al (2012), and Bartolacci et al (2012) also provide convincing evidence of the power of simulation as a methodological tool.

Constructing and modeling supply chains in practice, however, presents many challenges. Supply chains often involve "one or more families of related products", involving different entities or organizations that have different objectives, that are "highly interdependent when it comes to improving the performance of the supply chain in terms of objectives such as on-time delivery, quality assurance, and cost minimization." (Swaminathan et al., 1998). Hence, in order to effectively analyze supply chains using simulation, it is necessary to model the interdependence between different aspects of the model. Such interdependence may manifest itself in the demand for products, in the delivery of raw materials, in set up times, etc. Often, distribution of demand, delivery times, and set up times are not normally distributed, and must

be described using non-normal distributions such as the Gamma, Weibull, Beta, and other similar skewed distributions (Burgin, 1975; Wagner et al, 2009). Furthermore, it is possible that the demand for a given product has a certain marginal distribution (say Gamma), while that of another has a completely different distribution (say Weibull), but the two demand distributions are related. Thus, in order to analyze the performance and management of supply chains and similar complex systems, the ability to simulate random variates whose marginal distribution and dependence are specified is a necessary pre-requisite.

Currently, we do not have the ability even to completely specify such joint distributions, and the generation of such related random variables is extremely difficult. One possible approach for modeling the joint distribution of a set of variables with non-normal marginal distributions is to use copulas. The use of copulas for modeling complex supply chain relationships is not new. It has been previously used for modeling supplier default dependencies (Wagner et al, 2009) and to estimate the joint distribution of the disruption vector (Masihtehrani, 2011). The objective of this study is to demonstrate the viability of a method based on copulas for generating related random variates with specified marginal distributions and dependence structure for modeling supply chain inter-dependencies.

BACKGROUND

The ease with which random variates can be generated has improved considerably in recent years. This improvement can be attributed to improved hardware and software that is currently available (compared to just 15-20 years ago). Now, even standard desktop software such as Excel offer the ability to perform basic simulation without any other software. Software such as Crystal Ball and @Risk offer the ability to analyze complex decision analysis scenarios, and software such as Arena, GPSS, and ProModel offer the ability

to simulate complex systems. One of the crucial aspects of any simulation software is the ability to generate random variates from specified distributions in order to investigate the impact of changes in assumptions on the results of the analysis. Discussion on generating random variates can be found in practically all simulation textbooks. Readers interested in the technical details of algorithms are referred to the book by Fishman (1996), while those interested in the application of simulation are referred to the book by Law (2007).

While most textbooks offer a discussion of the generation of univariate forms of normal and non-normal random variates, discussion of multivariate random variates is invariably limited to the normal distribution. The generation of multivariate normal distribution is well understood and documented and many algorithms are available (see for example Fishman, 1996). Discussion of multivariate non-normal distributions, however, is another matter. Few algorithms for the generations of multivariate non-normal distributions are available due to the general complexity of non-normal multivariate distributions.

A few joint distributions for the bivariate Gamma and other non-normal distributions such as the Weibull and Exponential have been proposed (Kotz et al., 2000). Note that in these cases, it is assumed that the marginal distribution of the individual variables comes from the same family (such as Gamma, Weibull, etc.). Even then, these distributions are extremely complex. There are very few cases where the joint distribution of a set of variables whose marginal distributions are arbitrary (do not come from the same family of distributions) can even be specified. For example, consider a simple case where the marginal distribution of demand for a set of four products is given by the Gamma, the Uniform, the Normal, and Beta distributions, and that the demand for these four products are related. We currently do not even have the ability to specify the joint distribution of demand for the four products with the characteristics above. When the joint distribution is not specified, then it is impossible to derive

the conditional distribution or to generate related random variables for this specification.

One recent method for generating related non-normal random variates (Headrick and Sawilowsky, 1999) is based on the approach proposed by Fleishman (1978). This method generates a random variate from a normal distribution, and uses a transformation to create a new variate with a specified level of skewness and kurtosis. This method was later extended to generate multivariate non-normal random deviates (Headrick and Sawilowsky, 1999; Vale and Maurelli, 1983). However, this method is also not capable of producing all possible combinations of skewness and kurtosis and hence it is limited in its application. Further, the marginal distribution of random variates generated in this manner do not represent the true marginal distribution, and lack the ability to describe the probability density function (pdf) and cumulative density function (cdf). This implies that it would be impossible to derive the percentiles of the population from which these random variates had been generated (Tadikamalla, 1980).

In the context of operations management research, the inability to generate random variates from a specified marginal distribution that can be completely characterized by their pdf and cdf represents a serious shortcoming of this method. In many cases, the researcher may wish to change the parameters of the specified distribution to investigate the impact on the outcome. In addition, the inability to derive the percentiles for specified populations would make it very difficult to analyze issues such as service levels, etc. Hence, there is a need for methods that are capable of generating related random variates, with a specified dependence structure, and whose marginal distributions are non-normal (or a combination of normal and non-normal distributions). And in order for such a procedure to be useful, it must also be easy to implement. In the following section we describe the concept of copulas that can be used for this purpose.

The Copula Approach for Generating Random Variates

The copula approach is based on Sklar's theorem (Sklar, 1959) which states that for random variables $(A_1, A_2, \dots, A_k)$ with marginal cumulative distribution function (CDF) $F_i(a_i)$ ($i=1,2,\dots,k$), the joint CDF can be written as:

$$F(a_1, a_2, \dots, a_k) = C[F_1(a_1), F_2(a_2), \dots, F_k(a_k)] \quad (1)$$

where $C[F_1(a_1), F_2(a_2), \dots, F_k(a_k)]$ is a joint *copula* CDF with uniform marginal distributions. When $F_1(a_1), F_2(a_2), \dots, F_k(a_k)$ are continuous, the copula is also unique. In addition, the joint probability density function $f(a_1, a_2, \dots, a_k)$ can be written in product form as:

$$f(a_1, a_2, \dots, a_k) = \prod_{i=1}^k f_i(a_i) \times c[u_1, u_2, \dots, u_k] \quad (2)$$

where c is called the *copula* density, $f_i(a_i)$ are the marginal densities of A_i , and u_i is a uniform random variable. The joint density as shown in (2) also provides the ability to derive the conditional density of one or more of the random variables with respect to the other variables. For continuous distributions, the copula allows us to separately specify the marginal distribution of $(a_1, a_2, \dots, a_k)$ and the relationships between them, with the relationships being represented by the copula (Clemen and Reilly, 1999; Lindskog, 2000; Nelsen, 1991; Schweizer, 1991).

The primary applications of copulas have been to combine arbitrary marginal distributions into specified joint distributions that exhibit certain specified dependence or joint behavior. Nelsen (1995) and Schweizer (1991) serve as good introduction to the theory and application of copulas. A wide variety of copula functions have been investigated for combining non-normal distributions, both discrete and continuous. The selection

of a specific copula function depends on the specific problem under consideration. Some copula functions are well suited for describing bivariate distributions, but not for describing multivariate distributions. The specific characteristics of the joint distribution also vary depending on the specific type of copula selected. For our purpose, namely, generating random variates with specified marginal distributions and relationships, the multivariate normal copula is an effective approach.

The normal copula parameterized with product moment correlation matrix ρ can be written as:

$$C_{\rho}(u) = \phi_{\rho}^k \left(\phi^{-1}(u_1), \phi^{-1}(u_2), \dots, \phi^{-1}(u_k) \right) \quad (3)$$

where ϕ_{ρ}^k represents the joint CDF of a k -variate standard multivariate normal distribution with correlation matrix ρ , ϕ^{-1} represents the inverse of the CDF of the univariate standard normal function, and $(u_1, u_2, \dots, u_k)$ are uniform deviates. Now if we consider $(u_1, u_2, \dots, u_k)$ as:

$$[u_1 = F_1(a_1), u_2 = F_2(a_2), \dots, u_k = F_k(a_k)] \quad (4)$$

then the normal copula above can be re-written as:

$$C_{\rho}(u) = \phi_{\rho}^k \left(\phi^{-1}(F_1(a_1)), \phi^{-1}(F_2(a_2)), \dots, \phi^{-1}(F_k(a_k)) \right) \quad (5)$$

Thus, we are able to express the marginal distributions $F_i(a_i)$ of the original variables in the form of a multivariate normal copula. The next step in the process is to identify the relationship structure that results when the normal copula is used.

Traditionally, pair-wise product moment (or linear) correlations between the variables are commonly used to express relationships between random variables. The pervasive use of the linear correlation as a measure of relationship (or dependence) between variables can be attributed to its ease of use and the traditional assumption of multivariate normality. When the population is assumed to be multivariate normal, it is well

known that the relationship between the individual variables in the distribution is characterized by a linear relationship, and hence, the dependence structure between the variables is completely characterized by the pair-wise correlation matrix (Kotz et al., 2000). This however, is not true for multivariate non-normal distributions.

When the population is best described by a multivariate non-normal distribution the relationship between variables may be nonlinear in nature. Using linear correlation to measure the relationship between non-normal variables may result in an incorrect measure of the true dependence between the variables (Lancaster, 1982). In such cases, rank-based measures of dependence such as the Spearman's rank order correlation or Kendall's Tau can be used to measure dependence (Clemen and Reilly, 1999; Lancaster, 1982; Nelsen, 1991; Schweizer and Wolff, 1991). Unlike linear correlation, Spearman's rank order correlation and Kendall's Tau possess the desirable property that they are independent of the marginal distributions of the variables. These rank-based measures can be used as the index of dependence for many families of copulas (Clemen and Reilly, 1999). In this study we use Spearman's rank order correlation matrix to measure the relationship between the variables. The use of Kendall's Tau in place of Spearman's rank order correlation will provide similar results.

There is a direct relationship between linear correlation and Spearman's rank order correlation for the multivariate normal distribution. Let $R=(r_{ij})$ represent the $(k \times k)$ matrix of Spearman's rank order correlation and let $\rho=(\rho_{ij})$ represent the corresponding matrix of product moment correlation. Then, each element ρ_{ij} in ρ can be written as (Kruskal, 1958):

$$\rho_{ij} = 2 \text{Sin} \left(\frac{\pi r_{ij}}{6} \right) \quad (6)$$

Thus, if Spearman's rank order correlation matrix of the original variables is available, we can completely specify the multivariate normal

copula function described in (3). Once the copula function is specified, it becomes possible to generate related multivariate random variates with specified marginal distributions and dependence structure described by R(Clemen and Reilly 1999, Lindskog 2000).

The exact process of generating the multivariate random variables is as follows:

1. Identify the marginal distribution of $(A_1, A_2, \dots, A_k)$.
2. Construct $\mathbf{R}$, the Spearman's rank order correlation matrix of $(A_1, A_2, \dots, A_k)$.
3. Compute ρ using $\mathbf{R}$ as shown in equation (6).
4. Generate a row vector $\mathbf{x}$ of size k from a standard multivariate normal distribution with correlation structure ρ .
5. Convert each element in $\mathbf{x}$ into a uniform random deviate $u_i = \Phi(x_i)$ ($i=1, 2, \dots, k$).
6. Convert each u_i into the specified marginal distribution by using $F_i^{-1}(u_i)$ ($i = 1, 2, \dots, k$).
7. Repeat steps 4-6 for more values.

The values so generated will have marginal distributions $(F_1, F_2, \dots, F_k)$ respectively for $(A_1, A_2, \dots, A_k)$, the rank order correlation matrix specified in $\mathbf{R}$, and a joint distribution specified by the multivariate normal copula in (3). Note that each of the steps in the above process can now be performed by traditional methods: (1) Most simulation software (and Excel) provide the ability to compute the density and inverse of a diverse set of univariate marginal distributions and (2) The generation of the row vector $\mathbf{x}$ with specified correlation structure ρ can be performed by using Cholesky decomposition as described in Fishman (1986).

The copula based procedure described above is similar to the NORTA procedure that is described in Law (2007). The difference between the two procedures lies in the fact that the use of the Normal Copula approach provides a theoretical basis for specifying the dependence structure. One of the

difficult aspects of using the NORTA procedure is the ability to specify the correlation structure for the multivariate normal distribution that, when transformed, will result in the desired correlation structure for the transformed variables. In many cases, this may require extensive computation and solving non-linear equations of the order of $k \times k - 1$, where k represents the number of variables (Chen, 2001). By contrast, the copula based approach solves this problem by using rank order correlation and both the multivariate normal and transformed variables have the same rank order correlation, eliminating the need for the initial computations.

Finally, and perhaps most importantly, the copula based approach provides theoretical basis for describing multivariate data whose marginal distributions are not normal and exhibit certain dependence characteristics, while the NORTA procedure is intended only to generate random vectors. In this study, we have used the copula approach for generating random variables. In addition, it may be possible to use copulas for analyzing other situations in supply chains as well. Copulas have been used for modeling data from accidents (Yi and Bier, 1998), actuarial evaluations (Frees, et al. 1996), expert opinions (Jouini and Clemen, 1996), financial returns (Clemen and Reilly, 1999), and other situations. Hence, it is possible that in addition to providing a method for simulation related random variables, copulas may also offer the ability to model other complex situations in supply chains.

SOLUTIONS AND RECOMMENDATIONS

Illustrative Applications of the Copula Approach

In this section, we provide two illustrations of the application of the procedure based on multivariate normal copulas described above. To highlight

the ease of implementation, all computations were performed in Excel using Visual Basic on a standard laptop.

Generating Correlated Demand with Arbitrary Marginals

Assume that a researcher is interested in generating demand from a multivariate distribution with five variables, with the following characteristics:

- $A_1 \sim$ Gamma with shape parameter = 1 and scale parameter = 1 (Exponential);
- $A_2 \sim$ Gamma with shape parameter = 2 and scale parameter = 1;
- $A_3 \sim$ Beta with shape parameter = 2, scale parameter = 3;
- $A_4 \sim$ Beta with shape parameter = 3, scale parameter = 2;
- $A_5 \sim$ Normal distribution with mean = 0 and variance = 1.

These five distributions were selected to illustrate the ability of the copula-based procedure to generate widely varying marginal distributions. The first variable has a heavily (positively) skewed exponential distribution, the second variable comes from the same family as the first but has less skewness, the third variable comes from a different family (Beta) and is positively skewed (but the skewness is not as high as variable 1), the fourth variable also has a Beta distribution, but with negative skewness, and the last variable has a normal distribution. The generation of these vari-

ables, *individually and independently* is a simple matter. However, assume that the researcher wishes to generate random values that are correlated with rank order correlation matrix R provided in Table 1 (left panel). In this case, the researcher will have to use the copula based method that we have described in the previous section.

Using the parameters above, 10,000 values were generated in Excel using the copula procedure. Table 1 also provides the rank order correlation of the actual generated values (right panel). Comparing the two sets of correlations in Table 1 (specified and actual), it is easy to see that the copula procedure is able to maintain the rank order correlation of the generated values to be practically the same as the specified rank order correlations. Thus, the results of this illustration verify the fact that the copula-based procedure is capable of generating random variates with specified marginal distributions and specified relationships.

In the above analysis, we did not include the results when the variables are generated independently since, by definition, the variables would be uncorrelated. The following analysis shows the impact of the difference between the two procedures. Figure 1 provides a scatter plot of variables A_1 and A_4 generated independently and Figure 2 the scatter plot for the same variables generated using the copula approach. From Figure 2, it is evident that the copula based approach is very effective in preserving the strong positive relationship between the two variables; when the value of one variable is low, the value of the other variable is

Table 1. Specified and actual rank order correlation of demand data

Specified					Variable	Actual				
A_1	A_2	A_3	A_4	A_5		A_1	A_2	A_3	A_4	A_5
1.00					A_1	1.00				
0.50	1.00				A_2	0.51	1.00			
0.60	0.10	1.00			A_3	0.60	0.12	1.00		
0.80	0.20	0.70	1.00		A_4	0.81	0.21	0.70	1.00	
0.50	0.30	0.80	0.60	1.00	A_5	0.50	0.32	0.80	0.61	1.00

Figure 1. Scatter plots of variables 1 and 4 generated independently

also low and vice versa. But Figure 1 shows that if the values are generated independently, then no such relationship is exhibited; the value of one variable is independent of the other.

Table 2 provides the conditional probabilities of $(A_1|A_4)$ for the independent (left panel) and copula based (right panel) approaches. For comparison purposes, the middle panel provide the marginal probability of A_1 . As expected, when the variables are generated independently, the conditional probabilities of $(A_1|A_4)$ are almost identical to that of

the marginal probability of A_1 . By contrast, with the copula approach (right panel), we observe that when $A_4 < 0.25$, the probability of $A_1 > 2.5$ is practically zero. Similarly when $A_4 > 0.50$, the probability of $A_1 < 2.5$ is practically zero. When simulation supply chains, preserving these types of special relationships among variables that have a non-normal distribution can be critical to perform an accurate evaluation of the system. The copula based approach for generating related non-normal variable facilitates such evaluation.

Figure 2. Scatter plot of variables 1 and 4 generated using the Copula approach

Table 2. Conditional probabilities of $(A_1|A_4)$

	Independent				Marginal A_1	Copula Based			
	$A_4 \leq 0.25$	$0.25 < A_4 \leq 0.50$	$0.50 < A_4 \leq 0.75$	$A_4 > 0.75$		$A_4 \leq 0.25$	$0.25 < A_4 \leq 0.50$	$0.50 < A_4 \leq 0.75$	$A_4 > 0.75$
$A_1 \leq 1.25$	72%	72%	71%	73%	72%	99%	83%	38%	5%
$1.25 < A_1 \leq 2.5$	20%	20%	20%	20%	20%	1%	16%	45%	28%
$2.5 < A_1 \leq 3.75$	6%	6%	6%	5%	6%	0%	1%	14%	34%
$A_1 > 3.75$	2%	2%	2%	2%	2%	0%	0%	3%	34%

Simulation of an Inventory System

In order to illustrate the importance of considering relationships between variables when modeling systems, we consider a simple inventory problem consisting of four products with related demand. Please note that it is not our objective in this illustration to evaluate the efficacy of the inventory policy, rather to show the difference in results that could occur when correlated demand is used compared to when uncorrelated (independent) demand is used. It is likely that in supply chain management research, the models will be more complex. The characteristics of the four products are provided in Table 3 as well as the specified rank order correlation. The following assumptions are made about the inventory system: (a) Inventory

review is performed every 10 days, (b) Delivery lead time is a constant 10 days, and (c) There is no safety stock.

The order quantity is determined as Order Quantity = (Expected Demand during Protection Interval – Inventory on Hand), where Protection Interval = Lead Time + Time between Reviews (Markland et al., 1998). The expected demand during lead-time was computed using the population mean values from which the variates were generated (see Table 2). The inventory at the beginning of the simulation was initialized at ten days expected demand (average demand during time between reviews).

The above system was simulated for a period of 10,000 days. Two sets of demand were generated, one using the copula-based related demand and

Table 3. Characteristics of product demand

Distributional Characteristics				
	Product 1	Product 2	Product 3	Product 4
Marginal Distribution	Gamma	Gamma	Gamma	Gamma
Shape Parameter	1.00	0.80	2.00	1.50
Scale Parameter	500	500	200	400
Mean	500	400	400	600
Standard Deviation	500	447	283	490
Coefficient of Variation	1	1.12	0.71	0.82
Rank Order Correlation				
	Product 1	Product 2	Product 3	Product 4
Product 1	1.00			
Product 2	0.80	1.00		
Product 3	0.70	0.75	1.00	
Product 4	0.90	0.80	0.80	1.00

another where the demand for each product was generated independent of the other products, but using the same population parameters described above. The focus of the analysis was on inventory shortages. Hence, on any day where there was a shortage, the ending inventory for all the products was recorded. Table 4 provides a summary of shortages by product and provides the number and percentage of days a given product was short for both independent and correlated demand. The results for both types of demand are very similar. This is to be anticipated since this summary provides the results of shortages based on *the marginal distribution* of the demand for individual products that is the same for both correlated and independent demand. However, as discussed below, relying on this information alone can be very misleading.

Table 5 provides a summary of shortages *by the number of products*. Table 5 shows the total number of days and the percentage of days in which shortages occurred by number of products (0 to 4). The first row of the table (zero products with shortage) provides the percentage of days that

there was no shortage. The difference between the two results is significant, with independent demand showing that no shortages for only 59% of the days, while correlated demand indicates that there were no shortages in 72% of the days. This large disparity can be attributed directly to the fact that correlated demand accounts for the inherent and strong relationship between the product demand patterns. Hence, when there is (no) shortage in one product, there is a high probability that the other products will also have (no) shortage. Hence, the total number of days in which there is a shortage of products is much less than independent demand would indicate. In this case, independent demand significantly over-estimates the number of days of shortage.

The differences in the individual probability of a stock-out for a given number of products are also quite different. For instance, the probability that all four products will be short on a given day is 7% according to correlated demand, while with independent demand the probability is only 1%. In this case, independent demand seriously under-estimates the probability of having shortage

Table 4. Summary of shortages by individual product

	Correlated Demand		Independent Demand	
	Number of Days	Percentage of Days	Number of Days	Percentage Days
Product 1	1827	18%	1759	18%
Product 2	1876	19%	1713	17%
Product 3	1335	13%	1355	14%
Product 4	1627	16%	1649	16%

Table 5. Summary of shortages by number of products

Number of Products Exhibiting Shortage	Correlated Demand		Independent Demand	
	Number of Days	Percentage Days	Number of Days	Percentage of Days
0	7207	72%	5888	59%
1	940	9%	2365	24%
2	556	6%	1217	12%
3	575	6%	443	4%
4	722	7%	87	1%

in all products. In both cases, using the incorrect demand structure when simulating the inventory system leads to incorrect estimation of shortages. The results provided in Table 5 for correlated demand are more representative of the true nature of the system. Without using correlated demand, the conclusions that would be reached regarding the system would be quite different. These differences in the results have important implications for inventory policy. Thus, the use of the copula method for generating related random variates with arbitrary marginal distributions allows the decision maker to model the system more accurately.

IMPLICATIONS FOR PRACTICE AND RESEARCH

The copula-based method for generating related multivariate non-normal random deviates using copulas provides the decision maker the ability to specify (a) The marginal distributions of each of the random variables, and (b) The relationship between them (expressed as rank order correlations). The ability to specify each of these independently and explicitly provides the decision maker with practically unlimited flexibility in evaluating the impact of changes to the system parameters on outcomes. For example, it allows the decision maker to investigate the impact of changing the demand distribution of one product from (say) Gamma to (say) Lognormal, as well as to change the parameters of these distributions. In practice, this will facilitate the analysis of related components accurately and evaluate the sensitivity of the output to distributional assumptions.

It should be noted that in order to use the methodology proposed in this study, it is necessary that the relationship between the variables be captured adequately by the pair-wise rank order correlation matrix. Such a requirement is generally satisfied by random variables that have monotonic (strictly increasing or decreasing) relationships. However, if the relationship between two vari-

ables is non-monotonic (U-shaped or $\cap$ -shaped, for example), then neither rank order nor product moment correlation will accurately capture such a relationship (Clemen and Reilly, 1999). Under such conditions, it may be necessary to consider either transforming the variables in question or consider alternatives to the copula.

FUTURE RESEARCH DIRECTIONS

In this study, we have used the normal (or Gaussian) copula to generate the random variates. The normal copula is perhaps the best known and the easiest to implement of the alternative copula models available. But alternative forms of copulas may be better suited for modeling related variables in some scenarios (Wagner et al 2009). The investigation of the implementation of alternative copula models in a simulation setting presents an opportunity for future research.

CONCLUSION

Supply chain systems are more complex than the traditional manufacturing systems since they typically involve multiple products, vendors, production lines, and locations. These multiple products may have related demands, the multiple vendors may have related lead times, and the different production lines may have related set up times. And more importantly, most of these quantities also tend to have skewed marginal distributions. Hence, in order to accurately model these systems, it is necessary to have the ability to generate related random deviates whose marginal distributions may be non-normal. In this study, we propose a simple, effective, and easy to implement procedure based on the multivariate normal copula for generating related multivariate non-normal random deviates to effectively model, analyze, and evaluate supply chain systems with complex relationship among variables using simulation.

Using RFID and Barcode Technologies to Improve Operations Efficiency Within the Supply Chain

Amber A. Smith-Ditizio
Texas Woman's University, USA

Alan D. Smith
Robert Morris University, USA

INTRODUCTION

Management Throughout the Value Chain

Managers in today's business environment find themselves not only focused on internal processes such as production efficiency and employee relations, but also acknowledging the need to increasingly focus on management throughout the value chain. A number of researchers (Anderson & Dekker, 2009; Smith & Minutolo, 2014; Smith & Offodile, 2007; Wee, Peng, & Wee, 2010; Whitten, 2004) have identified some of the complex components of the supply chain to include global suppliers, contract manufacturers, company-owned product/service centers, third-party logistics providers, and transportation providers. Each relationship in the supply chain poses unique management opportunities and challenges. It is important for firms to understand the existing tools and strategies in the operations management field as well as the developing technologies and practices to better control costs and enhance efficiency in the supply chain. These same researchers frequently cite that the management of many companies are not operationally efficient (e.g., it can be seen from the cost of production is larger than needed, generating waste and non-value activities, and lack of vendor collaboration and integration, to name a few related issues). Proper management of their supply chains can

dramatically improve such efficiencies. In the following sections, a number of studies suggest that the use of RFID in supply chain management (SCM) can improve operational efficiency. This chapter briefly discusses the contribution of knowledge regarding the use of RFID in the operational efficiency of the company.

In order to stay competitive in the marketplace, firms must do whatever is necessary to gain an edge and create value for their product. The desired end goal is to get the right product to the right customer at the right price at the right time; to accomplish this chain of events firms must search for methods to achieve a competitive edge. In this increasingly global economy, competition for buyers can be cut-throat because of the easy access to the international market and global materials because of the internet. Also, because of the need for speed, space issues, and timing, supply chain agreements frequently expect the raw materials to arrive at the right warehouse or facility at the right time, not a week before or later. Needing to stop production because a part is missing is disastrously expensive; also loss of goods or theft is frequently a concern with companies. So the issue is raised, how can a company make improvements in the supply chain to be more efficient? Value is created for the client when the item arrives to the client on the right day. When an item is late or there are stock-outs there is the risk of the bullwhip effect occurring, when the client over-orders because they fear they might have

DOI: 10.4018/978-1-5225-2255-3.ch486

their order rationed. By tracking the orders and products with barcode and/or RFID technologies (Ha, Park, Lee, & Park, 2013; Kwok & Wu, 2009; Mateen & More, 2013; Mehrjerdi, 2009; Roberti, 2014), operational management have the enhanced ability to notice if there are inefficiencies within the organization and address them quickly, and if the capability allows, the client can see that they will receive their order exactly when they wished in the quantity that they desired. This technology can add value all throughout the supply chain, to include the warehouse, distribution, and returns management areas.

BACKGROUND

Importance of Supply Chain Management (SCM)

Supply chain management (SCM) is one of the critical decision areas that a firm must focus on in order to compete in the ever-changing world of business. As a number of authors (Berthon, Critenden, Desautels, & Pitt, 2010; Bhat, 2008; Biswas & Sarker, 2008; Browning & Heath, 2009; Cabral & Cruz-Machado, 2012; Cavaleri, 2008; Carvalho, Cruz-Machado, & Tavares, 2012; Chan & Kumar, 2009; Chongwatpol & Sharda, 2013) have pointed out, lean firms are charged with minimizing costs and increasing efficiencies from the beginning to the end of the value chain. Firms must take a much broader view of operations management that extends far beyond their factory or office walls. Decisions involving the entire value chain must be made and can be extremely difficult. Firms that are able to successfully manage the key areas of sourcing, supplier selection, and the design of supply relationships will often realize a competitive advantage. Research and observation has revealed that this advantage can come in the form of low costs, high productivity, quality, customer responsiveness, and innovation (Park & Min, 2013; Smith, 2010, 2015).

The various components of SCM will determine the cost structure relating to upstream operations and play a large role in risk mitigation. Supplier selection is one of the core decisions of structural cost management. Firms must decide whether these upstream operations should be executed internally or whether they should be outsourced to a supplier. The article makes reference to the “make-buy-or-ally” decision that management faces. A *make* decision would entail a firm integrating vertically and obtaining components from internal units. A *buy* decision is the decision to purchase inputs from another firm in an “arms-length” contract. An *ally* decision is a mixture of the two previous decisions whereby a buyer and seller remain separate entities but collaborate in a mutually-beneficial, long-term relationship. The appropriate supplier choice would be the option that minimizes production and transaction costs (Drejer & Riis, 2000).

Designing the buyer/supplier relationship involves contractual management controls that govern aspects such as specifying authority to make supply decisions, performance requirements, and rewards for achieving performance goals or sanctions for non-performance (Boerner, 2010; Hu, Wang, Fetch, & Bidanda, 2008; Jain, Benyoucef, & Deshmukh, 2008; Kennedy & Widener, 2008). In addition, informal controls such as performance feedback processes, joint budgeting/forecasting processes, and co-location of employees are developed to enhance the buyer/supplier relationship. Formal legal contracts as well as behavioral norms are established to improve the efficiency and effectiveness of the relationships. Enhanced uses of automatic identification and tracking technologies help reduce error and potential litigation issues in the supply chain.

Purpose of Present Chapter

This chapter will look at the impact of using RFID-embedded systems within a lean supply chain environment via a qualitative business case

study approach (Baxter & Jack, 2008). Managers need to be able to justify an augmentation of lean practice and real-time data with the use of RFID to improve supply chain management (SCM) and its ability to improve the goals of reducing waste and improving product visibility throughout the supply chain. By using a qualitative business case study approach, four local NE Ohio companies will be addressed to inspect how to make their supply chains more efficient with the use of RFID and barcode technologies, common examples of automatic identification and data capture (AIDC) technologies. Some of the companies have global implications, while others are more local in nature, but all have superior corporate reputations in NE Ohio; as well as extensively use RFID and barcode technologies to make their businesses more competitive and reduce time, materials, and labor waste. This chapter also discusses how these regionally headquartered companies strategically and operationally leverage their RFID-embedded technologies to create value for other organizations.

CASE 1: GOODYEAR TIRE AND RUBBER COMPANY

The Goodyear Tire and Rubber Company is headquartered in Akron, Ohio and is one of the world's largest tire companies. The company employs approximately 73,000 people, manufactures products in 53 facilities in 22 countries around the world. Supply chain efficiency has been a stated goal of any manufacturing based company, but when the company is relatively large and global in its reach, spanning many countries, supply chain efficiency becomes even more necessary.

Goodyear has been experimenting with RFID-related technologies since 1984, and began their first field trial with 3000 tires ("Goodyear's RFID technology ...," 2014). Since then they have improved upon these trials, embedding their patented RFID tags in their tires to eliminate errors in identification of tires in the forward and reverse

supply chain. Management at Goodyear generally acknowledges that RFID has a multitude of uses in the supply chain, to include tire production, warehousing, and sales and service. Goodyear is somewhat unique in that it is important that the process be fast, efficient, and seamless as possible in sending the tires to the right group, with the ability for the group to return the tires quickly. The company traditionally leases its tires to the racing participants; this leasing program has several benefits: The overall cost of the tire is lowered because old tires can be refurbished to be like-new, and there is less environmental impact in a continued buildup of discarded tires. RFID aids in this process, as the chip is embedded within the tire so that even if the tire is scuffed to the point that the numbers on the sidewall are unreadable, the chip eliminates any chance of user error in identifying a tire for refurbishment. At the beginning and end of each race, thousands of tires need to be moved from the facility to the race and back again, RFID ensures that each team on each end receives the right tires.

What started out as a method of tire identification, it expanded to include information about specific tire data to improve vehicle performance. In 2012, Goodyear explained company plans of making tires more intelligent to the point that they are feeding back real-time information to the driver. This feature added value to the tires for the end-product user, creating a need for the product, creating more demand for these services in the supply chain. An accurate log of each tire's activity was hard to promise prior to RFID, now the company can without a doubt state the chain of each tire's life.

Goodyear has used this technology to gain a competitive edge in the truck market. Using RFID in tires, the tires can eliminate the need to read sidewall markings on tires, instead using a scanner the information can be read and instantly recorded. If stolen, the tires can be traced easier and tire management and tire security is improved. Goodyear and the truck fleet owner can link into the Goodyear FleetOnlineSolutions™

fleet management system to easily locate service providers if needed, the service providers can see contract details and tire information easily. The fleet management system takes care of invoicing and stock control and ensures that customers are charged according to their agreements and are invoiced accordingly.

CASE 2: SHERWIN-WILLIAMS, INC.

Sherwin-Williams, headquartered in Cleveland, OH, was receiving feedback from its clients that bar codes were needed to help with inventory. In order to maintain these relationships, Sherwin-Williams implemented a custom print-apply bar code labeling system (“Are bar code labels a ...,” 2016). To increase efficiency in the supply chain, retailers needed bar code labels on the cartons the products were shipped in. This ensures a quick scan with a reader to be sure the carton goes to the right place, without the need to slow down the process with a manual read. The process is complicated for the company, at least in part due to the condition of carrying the products different retailers were demanding different information on the labels depending on what was needed to make their supply chains more efficient. These bar codes include product information, description codes, part numbers and more for each of the customer’s requirements, which was necessary to move products through the that retailer’s warehouse and distribution systems quickly and easily.

The company has orders that are not consistent so it can be a challenge trying to balance everything to ensure that long wait times aren’t happening, stock-outs weren’t occurring, and product quality remained high. Typically, orders would range from as few as 2000 cans to 300,000 cans or more. To comply with the retailer’s requirements Sherwin-Williams had to install parts of the bar-code labeling system on five lines of its manufacturing facility, with a linked PC network that could access all of the print/apply systems simultaneously.

In order to make sure the right information is on the barcode, at each of the five stations of the facility an operator enters the order number, which tells the manufacturing line what information goes into that manufacturing line. The linking back to the main computer systems, both fixed and mobile devices, ensures the right product is used at the right time, with the batch and data numbers to link back to the right process, and all of this information is attached to the barcode that is printed and placed on the cartons.

CASE 3: SURGERE COMPANY

Surgere is a small business based out of Green, OOH that focuses on supply chain optimization by improving and reducing packaging, and using efficient packaging to make the supply chain more efficient. Surgere’s clients include Best Buy, Timken, and Whirlpool. Surgere uses RFID-related technologies that are linked to computer programs to log and track packages, using real time information to know where a package is and be able to tell when a package is delayed or missing, if applicable (“SRFID - container tracking and management ...,” 2016). Knowing about issues occurring simultaneously allows management the means to handle most issues quickly and be proactive in order to not waste additional time. In the background, the linked software collects and organizes the data to interpret and dwell on turn times and analyze data in order to work towards full fleet utilization. The ongoing value of RFID-embedded systems includes asset management, loss prevention, improved productivity, analytics, and cost reduction.

RFID-related technologies usually constitute improvements on barcode technology, primarily because instead of an employee scanning one barcode at a time, RFID readers can quickly process hundreds of tags at a time. Wireless transmission of Surgere’s tag information logs and tracks information and provides real time information about shipment details. The reusable containers and

racks reduce waste and can be tracked throughout the supply chain process so that management can see the trends in the supply chain and look for opportunities to improve. By automating the process and adding RFID tags, using electronic product codes (EPCs), allowing universal identifiers to give unique identities to items with RFID tags; ultimately, productivity is improved and delays may be avoided.

CASE 4: THE KENNEDY GROUP

The Kennedy Group is located in Willoughby, OH and is noted as a supply chain optimization company that specializes in RFID technology. The Kennedy Group has many different types of tags depending on the nature of the business, to include multi-use or single-use tags. Different industries have different needs, such as a bakery likely needs reusable trays and racks because those have a high costs and a 30% loss rate. Higher cost items likely need constant monitoring to be sure that the items are exactly located in the supply chain where they should be. Retail food distribution has unique needs, such as a need to link a product back to a shipping container should a recall happen in the future. The Kennedy Group can aid in RFID-related implementation needs, especially in the industries of bakery, retail food distribution, manufacturing, industrial, and warehouse and logistics management. Food distribution sensors may need the ability to track temperature of a package, whereas warehouse and logistics management needs the ability for forklift reader integration. A firm only wishes to pay for the services that the specific firm needs, there is no value in paying for additional unnecessary technology that would add too much cost onto the product; a classic value-added proposition common in business operations.

MANAGERIAL IMPLICATIONS

Related AIDC-based technologies, most notably RFID and barcode technologies are invaluable in the operation and supervision of a company's supply chain. However, management typically has a difficult choice for a firm's management is trying to decide the system that will create the most value for the organization. As noted above, Sherwin-Williams was successful using barcodes and barcode readers to track the products throughout the supply chain. Goodyear decided to go with a more advanced system of RFID, likely because the cost of tires, especially racing tires, is much greater than the cost of cans of paint. The Kennedy Group and Surgere are two companies that can meet the needs of the companies using RFID or even barcode technology.

The basic cost/benefit issue is, then, how should a firm decide which method is best? Barcodes are universally accepted, simple, and low cost. Scanners are widely available and affordable. Barcodes are everywhere in the supply chain, but due to the physical dimensions there may be limitations on the amount of information that can be placed on a barcode. For retail applications, a barcode may only note the product type and the manufacturer.

Barcodes require a direct line of sight to be read, and can only be read one at a time which can be labor intensive. The barcode must be on the outside of the package to be read, which means there is the risk that the barcode becomes damaged and unreadable. Barcodes are easily counterfeited, but they do come at a very low cost, they can be made for a fraction of a cent or even a few pennies. Barcodes are best for closed loop supply chains and process manufacturing such as Sherwin-Williams where liquids and metals are used. Liquids and metals cause interference with certain radio frequencies, so RFID may not be effective for these industries.

RFID is more expensive yet has dynamic data that can read, write, update and even ac-

tivate the next step in a chain of events. RFID can track lifespans of a product or even track temperatures of products. Some RFID units can be reprogrammed for repeated use, or they may be single use only. Active data RFID include a battery and will automatically send data back to the programs; passive RFID is without a battery and only submits information when the product is within range of a reader. Unlike barcode readers that require a line of sight, RFID readers only require being within 20-40ft. and the readers can read through packages, therefore reading hundreds of chips at a time (Chongwatpol & Sharda, 2013; Delen, Hardgrave, & Sharda, 2007). Active RFID tags are expensive, ranging from US\$5-50 per unit. This is the option that Goodyear has chosen for the racing tires because of the need of being able to constantly access the tires information and location. Single trip and multi trip passive RFID chips are cheaper, ranging from 10 cents each to US\$4 ("RFID solutions," 2016). These are likely the options chosen for the majority of items at retailers in order to keep costs down, yet still have enough visibility and tracking options in order to view the supply chain process and look for areas of opportunity. Primarily due to the ease of readability, RFID is often the preferred choice in a complex supply chain, especially one with high volume transactions. Especially for organizations looking to track products at the unique item level, RFID outperforms barcodes especially when considering labor costs, loss, and theft.

Management of each firm must consider their unique needs and react accordingly. A supply chain management tracking system that Sherwin-Williams uses would not be effective for Goodyear, which demonstrates why each company reacts differently for their own supply chain management. A major issue is always cost, because paint is a product that has a high amount of competition, Sherwin-Williams has to be sure that any method that they use in their supply chain will be able to be absorbed into the cost of the product or with low additional added cost. For racing tires, the value isn't completely in the price though cost in a minor

factor, the value for the racing consumer is added benefits. Both companies likely wish to monitor the location of the product in the supply chain, but Goodyear's clients would likely be willing to pay an additional price for RFID tracking on the field, which Goodyear can also use this RFID technology to track the tires within the supply chain. As mentioned, Goodyear's services are unique in that there is a lot of forward and reverse logistics occurring, because of the increased risk of loss and theft an active RFID tag is almost necessary to keep the process flowing smoothly.

FUTURE RESEARCH DIRECTIONS

Improving efficiency in the supply chain by using bar code and/or RFID technology is a valuable option for all companies, although some smaller companies may prefer to continue to manually track their operations within the supply chain. Typically, suppliers track their products using mainly barcodes, but that is where the tracking stops until the USPS tracking begins. Intermediaries or warehouses repackage these products in customized fashion to suit the individual needs of retailers and/or manufacturers. Within each firm's supply chain, much of the inventory control is manually in smaller firms and done automatically to some degree in larger firms. Obviously, there is usually some level of confusion as items flow from the ordering phase, to the processing phase, to the shipment phase, to the receiving phase by the ultimate buyer. Both large and small organizations must decide if investing in barcode and/or RFID technology internally will make the efficiency/profit tradeoff a viable option. The case study described in this chapter, hopefully, demonstrates a company's efficiency through increased productivity, reduced failure, profit, as well as other types of improvement. Ultimately, all organizations need a better system than the clipboards and filing cabinet systems as the products flow through the various phases of the firm's supply chain.

CONCLUSION

Manual tracking of goods throughout the supply chain is rarely effective except in very small businesses. As the business grows larger, barcode and/or RFID technology is needed to reduce the possibility of stock-outs, the bullwhip effect, reduce loss, theft, and various other complications of the supply chain. Due to the various costs involved, a business needs to evaluate what system would work best in order to make their own supply chain effective, and then use the services of The Kennedy Group or Surgere to improve the flow of goods in the organization. In the last few years, more and more companies are integrating RFID or barcode technology into their planning, since it has been proven to significantly impact supply chain performance. Substantial benefits can be gained by implementing RFID-embedded technologies to improve identification and improve the movement of products, shipments, and assets.

KEY TERMS AND DEFINITIONS

Automatic Identification and Data Capture Technologies (AIDC): Types of AIDC-related technologies to leave the human element out of the data collection and storage functions of information derived from manufacturing, integrated through the manufacturing process, types of authentication concerns and/or e-security strategies, and relationship links to customer profiles. Typical types of AIDC include, bar-coding, RFID, magnetic strips, touch memory, and smart cards.

Barcoding Technology: A long-term and very reliable type of AIDC technology, it is known for its very accurate and economical approaches to identity products and machine readable information from a variety of manufactured goods and services. Most barcodes use a type of standardized bars and spacing coding or symbology that is certified by an international standards body (GS1 System). This system provides for the universal global acceptance of many types of barcodes designed for a variety of shipping and identification applications. Example barcode formats that are in common use today include EAN/UPC, GS1 DataBar, GS1-128, ITF-14, GS1 DataMatrix, GS1 QR Code and Composite Components.

Electronic Product Code (EPC): EPC is a universal identifier that gives a unique identity to an item a RFID tag is affixed to. The identity is made to be unique so that each object is identifiable within the objects' field.

Operations Efficiency: Improving efficiency and reducing waste is a major challenge for hospitals and other patient care facilities looking to lower the cost of providing healthcare services. Far and away the largest contributor to operational

costs in this industry is patient care activities. Since most clinical decisions involve managing products and medical supplies, finding ways to more efficiently manage supply chain activities can have a big impact on overall operational performance.

RFID-Embedded Technologies: RFID technologies are types of automatic data capture techniques that use a combination of active and passive senders and receivers to collect and store codified information for further uses. The implementation

of such technologies should lead to improved managerial and/or supply chain performance. On the surface, there appears to be few drawbacks to implementing such technology into a production process, assuming it enhances performance and improves output of the product. The main issues surrounding the RFID applications are whether the initial costs and labor required to utilize this technology are worth it, and will result in a positive outcome of revenues.

The Business Transformation Framework for Managers in Transformation Projects

M**Antoine Trad***IBITSM, Switzerland***Damir Kalpić***University of Zagreb, Croatia*

INTRODUCTION

A decisive business decision in the business transformation of a traditional business environment into an automated business environment is the profile of the business transformation manager (BTM), who should be supported by a holistic framework (Trad & Kalpić, 2001; Trad & Kalpić, 2014a). The BTM's profile and the needed data modelling skills are essential for managing data models' in business transformations. This research chapter and the related research publications deal with business transformation projects (BTP) complexity as well as the support for the BTM's selection and the underlined BTP architecture. The proposed framework promotes the needed business transformation data architecture and modelling skills to insure success: 1) artefacts; 2) components; 3) architecture; and 4) modelling concepts.

The success of a business transformation project (BTP) depends on how an enterprise architecture, data architecture and modelling activities are synchronized (IMD, 2015).

That is why the implementation of such BTPs requires significant knowledge of data architecture and modelling techniques. The author has based his research on many credible research sources of information like the Gartner Inc. and many others. The main fact is that only a small percentage of business organizations successfully terminate innovation-related BTPs; another important fact

is that business environments, which have a good data architecture and modelling concept, will gain a substantial business advantage (Tidd, 2006; Tidd & Bessant, 2009).

The data architecture and modelling module is a part of the Selection management, Architecture-modelling, Control-monitoring, Decision-making, Training management and Project management Framework (SmAmCmDmTmPmF, for simplification in further text the term *Environment* will be used), that supports the BTP's activities. As shown in Figure 1, the data architecture and modelling concept interacts with all the enterprise's architecture phases, using the data building blocks or the holistic brick (Trad & Kalpić, 2014a).

BACKGROUND

What is an architecture framework and more specifically, what is a data architecture and modelling module or concept? In general an architecture framework (The Open Group, 2011):

1. Is a foundational model, or set of classes/entities, which can be integrated in various architectures;
2. Describes a method for modelling a systemic view of the business enterprise in terms of a set of data building blocks, it should also show how the data building blocks and code building blocks collaborate;

Figure 1. Enterprise architecture cycles and the data access building blocks
Trad, 2015a; Trad, 2015b.

3. Contains a set of tools and provides a common vocabulary;
4. Includes a list of recommended standards and compliant products that can be used to implement the building blocks;
5. Includes a data architecture and modelling concept that refers to various techniques for the integration of different data models and data sources. Where this concept is based on data building blocks.

The global research topic's and final research question (hypothesis #1-1) is: "Which business transformation manager's characteristics and which type of support should be assured for the implementation phase of a business transformation project?" The targeted business domain is any business environment that uses: 1) internet technologies; and 2) frequent transformation iterations. For this phase of research the sub-question (or hypothesis #2-3) is: "What is the impact of the data architecture and modelling concept on

enterprise architecture and business transformation projects?”

MAIN FOCUS OF THE ARTICLE

In this research phase the author target the data architecture and modelling concept's usage that is a part of the Architecture module (Am), and he tries to prove that such a concept can be built on a loosely coupled architecture (Trad, 2015a; Trad, 2015b).

Data Management and Complexity

Chaotic and complex data architecture and modelling concepts can cause failures, where business environments have complex data architectures, as shown in Figure 2 (IBM, 2015a).

RESEARCH METHODOLOGY AND DESIGN

As shown in Figure 3, the *Environment's* research methodology focuses on the impacts of the mechanistic enterprise's architecture integration and uses a mixed hyper-heuristics based methodology (Vella, Corne, & Murphy, 2009). This methodology offers the possibility to select a BTM and also offers guidance for the BTP's management (Trad & Kalpić, 2001); it proposes also a data architecture and modelling concept to be used by BTPs (Trad, 2013a).

Business transformation research projects and business engineering research projects use a proof of concept or prototyping to establish the: 1) viability; 2) technical issues; and 3) needed recommendations (Camarinha-Matos, 2012).

The research's sub-project's proof of concept is used to prove the feasibility of the data architecture

Figure 2. Structure of an enterprise architecture document and its relation to the data architecture and modelling concept

The Open Group, 2011; Trad, 2015a; Trad, 2015b.

*Figure 3. The mixed method flow diagram
Trad & Kalpić, 2013a.*

*Figure 4. The proof of concept's overall diagram
Trad, 2015a; Trad, 2015b.*

and modelling concept, as shown in Figure 4. The proof of concept is based on a transaction management case that uses data class diagram, as shown in Figure 5. In general data packages are defined in the preliminary phase and then calibrated in the requirement and business architecture phases. At the business analysis level, the data class diagram permits the definition of the fundamental BTP's data artefacts.

BUSINESS DATA ACCESS ARCHITECTURE AND AGILITY

Enterprise Architecture Principles

Enterprise architecture principles are divided into four categories (The Open Group, 2015a):

1. Business architecture principles.

2. Data architecture principles.
3. Application architecture principles.
4. Technology architecture principles.

The BTM must define the BTP's data architecture principles for various data sources that can be composed of the following characteristics (The Open Group, 2015a):

1. Data sources are shared in real-time.
2. Data sources are accessible in the intranet and extranet.
3. Data sources are of good quality and are trusted.
4. Data architecture and modelling have a common vocabulary.
5. Data security is implemented in all data sources.
6. Business processes that use data sources have to be standardized.
7. Data source management is managed by a defined role.
8. Data sources must be protected from unauthorized access and modification.

In this chapter the author focuses on the data architecture principles that have an important influence on all other architecture principles.

Data Strategy Principles

The data architecture and modelling strategy should be based on well-defined principles, like (IBM, 2015a):

1. Data have to be easy to enter and must be accurate.
2. Data collections are based on data modelling concepts.
3. Data must be available to business personnel.
4. Business processes for data management have to be automated.
5. Data should not be redundant.
6. Data have to be recorded accurately and must be auditable.
7. The cost of data collection procedures have to be optimized.
8. A data architecture and modelling concept must adopt standards for common data models.

Figure 5. The proof of concept's class diagram package
Trad, 2015a; Trad, 2015b.

The Role of Data Standards

The *Environment* uses data technologies and existing data standards that include: 1) relational database standards; 2) vertical industry documents' standards; 3) business process standards; 4) data governance standards; 5) business services standards; 6) extensible mark-up language standards; 7) object oriented and object relational modelling standards; and 8) resources description standards. Standardization for inter-operability can be achieved by using an Enterprise Service Bus (ESB) and its Extract Transform Load (ETL) module (Tamr, 2014). The evolution of technology standards, like the service oriented architecture standards, have enabled data architecture and modelling concepts to become more receptive to development and integration with various standards. Standardized BTPs have to be inter-operable and their focus must be on their: 1) data models; 2) data architectures; 3) modelling concepts; and 4) data monitoring platforms. Regardless of the business domain, executive management understands the immense need for agility and the integration of data architecture and modelling concepts. The *Environment's* data architecture and modelling concept helps in establishing a unique architecture (Trad, 2015b).

UNIFYING THE DATA SOURCES AND ENTERPRISE DATA NORMALIZATION

Enterprise Service Bus and Enterprise Application Integration

BTPs must use Enterprise Service Buses (ESB) to glue the various data sources of the business environment, through the use of the technology stack and data connectors, which permit a holistic data services' management (Erl, 2008; Erl, 2009)

Extraction, Transform and Load

Extract Transform and Load (ETL) processes are defined as accessing data stored in various locations and transforming them in order to enable their unification, quality or normalization. The *Environment's* data architecture and modelling concept, proposes the separation of data processing activities; that enables data services to access data without bothering about various data sources' complexities. The *Environment's* data architecture and modelling concept insures: 1) intra (or extra) data transparency; 2) managing accessibility; and 3) data quality control (Tamr, 2014). As shown in Figure 6, the ETL processes are responsible for the

Figure 6. Various data sources
Tamr, 2014.

access of data from heterogeneous data sources. The challenge lays in the real-time data transformation and normalization processes (Trujillo & Luján-Mora, 2003).

Data Transformation Models

The Meta-Model

This research sub-project's proof of concept uses a meta-model to show the relationships between the BTP's different types of data models and data sources. This BTP's meta-model contains descriptions on how data sources are handled in the newly transformed business system's and of the types of used data structures like (IBM, 2015a):

1. The physical structure uses physical classes and their attributes to model the data schema. Such class models use the enterprise application integration hub to transform data sets.
2. The establishment of relationships between different physical data classes.
3. Data transformation rules and mappings at the class attribute level.
4. Interface drivers, constraints and timing rules for interaction diagrams.
5. Global mapping technique and object oriented relations.

Normalization and Inter-Operability

A BTP data architecture and modelling concept must be based on various standards that are all in turn based on the eXtensible Markup Language (XML) technologies; XML enables ontology-mediated interoperability that is based on data schemas. Schemas enable the alignment by defining common data structures. Data architecture and modelling conceptual schemas are used in the mediation module that describes the semantics of data sources and destinations. Data architecture and modelling conceptual normalisation is a three layered approach for information representation,

as shown in Figure 7, the three layers for data integration include: 1) syntax checking; 2) data modelling; and 3) semantics control. The proof of concept uses the normalisation conversion modules that include a set of tables to automate the data translation process (Fodor, Dell'Erba, Ricci, Spada, & Werthner, 2002).

The Resources Description Framework's (RDF) database system links open data structures and is based on semantic technology (Curé & Blin, 2014). The role of metadata is important due to evolution of business, technology and the Web; where XML is the standard for data interchange, but XML schemas lack the capacity to express semantics and cannot formulate the document's structure. Currently there is a lack of semantic interoperability regarding current metadata standards. In the use of semantic web technologies, ontologies are produced to describe the semantics of a particular metadata format. Unfortunately XML data that have a specific metadata format cannot work with an ontology that forces the conversion of XML data to RDF instances. A generic approach can be implemented to transform XML data into RDF instances in an ontology-compliant manner. A mapping document supports the links between an XML Schema and Web Ontology Language (OWL) ontology (Van Deursen, Poppe, Martens, Mannens, & Walle, 2008).

DATA ARCHITECTURE AND MODELLING

The BTP needs enterprise, solution, technical and infrastructure architectures to support an enterprise information system's architecture that has many interrelated aspects, including applications, hardware, networks, business processes, technology choices, and data architecture. As shown in Figure 8, the data architecture is a layered set of models which provide a solid foundation for strategic initiatives such as (IBM, 2015a):

Figure 7. Stages of conceptual normalisation process

Fodor, Dell’Erba, Ricci, Spada, & Werthner, 2002.

1. The data architecture and modelling strategy that defines the business’s principles and objectives for the transformed data.
2. Business processes’ transformation.
3. Decisions on the BTP’s actions.
4. Integration, data storage management and reporting initiatives.

The Class Diagram

In data architecture and modelling, the main data class diagrams, as shown in Figure 9, are to be defined at the initial phase and then calibrated in the requirement and business architecture phases. At the management levels, the data class diagram permits the essential BTP’s data architecture and modelling concepts to be designed, without taking into account the enterprise’s complexities and resistances. This managerial or business architecture level enables the BTP team to concentrate on the business aspects (TOGAF Modelling, 2015b).

Mapping Concepts

The data architecture and modelling are based on the “1:1” mapping concept, this concept helps in achieving the assertion of the BTP’s data models (Kabzeva, Niemann, Müller, & Steinmetz, 2010).

Data Solution Blocks

As shown in Figure 11, the *Environment* uses the data architecture and modelling concept that includes the pattern on how to integrate data solution blocks which are instances of the data building blocks (Tripathi, 2011).

Figure 8. Data architecture and modelling is a layered set of models
IBM, 2015a.

Figure 9. The proof of concept's class diagram
Trad, 2015a; Trad, 2015b.

Transactions Data Modelling

The BTP must put important considerations on technical assertion, governing, control, access management and monitoring of business transactions that are based on the Model View Controller (MVC) pattern, as shown in Figure 12. Business transactions use the following standards: 1) the policy framework (Oracle, 2015a); and 2) busi-

ness messaging that is needed for domain-specific integration (Oracle, 2015b; OASIS, 2009).

Architecture Development Method's Integration

The usage of the architecture development method's phases in the BTP's data architecture and modelling is done in the following phases (The Open Group, 2014a):

Figure 10. The proof of concept's data building block diagram
Trad, 2015a; Trad, 2015b.

*Figure 11. The proof of concept's data solution block diagram
Trad, 2015a; Trad, 2015b.*

*Figure 12. The proof of concept's model view controller diagram
Trad, 2015a; Trad, 2015b.*

1. **Vision Phase:** In this phase the concept of the basic set of data building blocks is defined.
2. **Requirement's Management Phase:** Insures that any changes to the BTP's requirements are handled in the appropriate data architecture and modelling building blocks (Kabzeva, Niemann, Müller, & Steinmetz, 2010).
3. **Business Architecture Phase:** Receives the active data building block instance(s) and enhances its contents.
4. **Information System's Phase:** Receives the active data building block instance and enhances the data architecture and modelling to: 1) integrate the detailed project plans; 2) the design of the needed real artefacts; 3) the analysis of the needed real artefacts; and 4) the implementation and testing of the needed real artefacts.
5. **Change Governance Phase:** Receives the active data building block instance and enhances the data architecture and modelling logging interfaces for the: 1) project plans changes; 2) modifications of the architecture vision; etc.

Data Modelling

A data model is needed to describe the structure and relationships among a set of data managed in the BTP and stored in a data management system. The most common is the relational model that is often represented in entity-relationship diagrams or class diagrams; these diagrams basically show data entities and their relationships. The data architecture and modelling concept for a BTP can be seen as a data architectural view (Merson, 2009); where the modelling process incorporates various conceptual views.

Data Dissemination View

The purposed data dissemination diagram shows the relationship within the proof of concept: 1) data

entities; 2) business data services; and 3) application components/services. This diagram as shown in Figure 13, presents the logical data entities to be physically managed/accesses by application components or services. That permits a flexible architecture and modelling of the data sources. This diagram includes data services that abstract various data sources (TOGAF Modelling, 2015a).

Data Lifecycle View

The proof of concept's data lifecycle diagram manages the business processes' data throughout their lifecycle, from architecture, modelling, usage to disposal, within the constraints of the business process. The data are loosely coupled with business processes and that allows the definition of common data models enabling an effective data resources' sharing. Each data model must have its status that contains the transitions and the gaps between phases. A phase's state must contain a stable data model, where the data architecture and modelling lifecycle enables a qualitative design of the related business entities. The resultant data models must be atomic or simple in order to (re) engineer the BTP's business processes (TOGAF Modelling, 2015c).

Data Migration Diagram

The proof of concept's data migration diagram presents the flow of data between the business systems' various data sources; it serves as a view for the BTP's data auditing and traceability map. The data migration diagram is enhanced through BTP's iterations (TOGAF Modelling, 2015d). A mapping table was developed to show the relationships between various data points (source, intermediate or destination), as shown in Table 1.

Data Security Diagram

Design of data architecture and modelling are the most important activities in the BTP and the transformed business data are a very important

*Figure 13. The proof of concept's data dissemination view
Trad, 2015a; Trad, 2015b.*

asset for the enterprise; that implies that the transformed business data security is an ultimate goal, as shown in Table 2. The proof of concept's data security diagram presents the BTP's actors' roles for transformed business data. A matrix is used to present the mapping relation between the role

and the transformed data entity. The data security diagram includes all external accesses which may have access to the business system's data (TOGAF Modelling, 2015e).

Enterprise Data Architecture Models

The proof of concept's data entities or classes are the basis for a variety of enterprise's data models, as shown in Figure 13 (IBM, 2015a), that contains the following technical domains:

1. Data quality;
2. Interoperability;
3. Logical data model.

Table 1. The names of the entities that are mapped from the source to the destination media

Source Class/Entity/Object	Destination Class/Entity/Object
Catalog	dCatalog
Customer	aCustomer
Environment	dEnvironment
Payment	dPayment
Procurement	dProcurement
Product	dProduct
Transaction	dTransaction

Trad, 2015a; Trad, 2015b.

Table 2. The actor data access rights mapped to the type of domain

Actor	Marketing	Finance	...
Catalog	CRUD	_R_	
Customer	_RU_	_R_	
Environment	CRUD	CRUD	
Payment	_R_	CRUD	
Procurement	CRUD	_R_	
Product	CRUD	_RU_	
Transaction	_R_	CRUD	

Trad, 2015a; Trad, 2015b.

Data Architecture and Modelling Exchange

Inputs

The inputs for this phase are: 1) Data principles; 2) Request for architecture work; 3) Statement of architecture work; 3) Architecture vision; 4) Relevant technical requirements; 4) Gap analysis; 5) Baseline business architecture; 6) Target business architecture; 7) Baseline data architecture; 7) Target data architecture; and 8) Re-usable building blocks.

Outputs

The outputs for this phase are: 1) Statement of architecture work; 2) Baseline data architecture; 3) Validated data principles; 4) Target data architecture; 5) Business data model; 6) Logical data model; 7) Data management process models; 8) Data entity/business function matrix; 9) Data interoperability requirements; and 10) Viewpoints addressing key stakeholder concerns.

Business Transformation Management's Data

Data Architecture and Modelling Gap Analysis

The data architecture and modelling concept's requirements must be tracked for the evolution

of the BTP's architecture development cycle(s). Data architecture and modelling concept's routine report must contain: the statuses, achievements and impact analysis. The impact analysis gaps present where the data architecture and modelling concept needs to be changed and which data building (and solution blocks) to be included. Changes in the data architecture and modelling concept implies a change in the data building and solution blocks. A key step in validating a data architecture and modelling concept, is to verify the artefacts and to find the need for change. Types of data architecture and modelling concept's gaps' need for change are (The Open Group, 2015b): 1) data not found by the data services; 2) wrong data is delivered; 3) data unreachable; 4) data was not correctly stored; 5) data cannot be used; 6) bad data relationships; and 7) those that include the stakeholder's concerns.

THE PROOF OF CONCEPT

The *Environment* serves as the proof of concept's template and is based resources from The Open Group's Architecture Framework (TOGAF) (Trad & Kalpić, 2014b). The *Environment* contains five modules which can be launched independently; these components are used to tune the characteristics of the BTM's profile and to support the BTP's implementation phase. The *Environment's* are interconnected and have a pool of critical success factors. The data architecture and modelling

Figure 14. The proof of concept's data enterprise models
The Open Group, 2014X.

concept can be used in a real world system and this feature is the research's major business and managerial benefit (Wes, 2001). The *Environment's* data architecture and modelling concept structures, as shown in Figure 14, serve many functional domains and in this proof of concept

the functional domain are information analysis and decision making of a business transaction's log; where the data that results from business transactions are logged and used in the data analysis process, as shown in Figure 15.

Figure 15. The proof of concept's data interface view
Trad, 2015a; Trad, 2015b.

Information Analysis

The data architecture and modelling concept proof of concept took into account the integration of information analysis processes that are used by a virtual user who simulates a business analyst (Trad, 2015c). In this proof of concept a spreadsheet was built to use various data sources that fed the prototyped business transactions system, as shown in Figure 15.

Layers

The prototyped business transaction is based on the proof of concept's class model, as shown in Figure 16.

As shown in Figure 17, the data architecture and modelling proof of concept's layers are:

1. The client layer that contains the following packages based on: Microsoft Excel, Flat Files Interfaces and a Client web interface (Trad, 2015c).
2. The services layer that contains a data services hub.
3. The data management layer that contains the following packages: an entity relational

model, an extensible mark-up language transformer and a NoSQL database interface.

4. The control-monitoring layer contains a generic logger interface.
5. The platform layer that contains the following packages: an enterprise service bus, an object database connector, and a java database connector.

SOLUTIONS AND RECOMMENDATIONS

This chapter's and its proof of concept's list of the most important technical and managerial recommendations:

1. The BTMs should be supported with a set of data architecture and modelling concepts and tools that can be easily integrated with the defined data architecture principles (Trad & Kalpić, 2014b; IBM, 2015a).
2. The role of data standards is important; today there are many standards concerning data architecture and modelling concepts. The BTM must propose a solution on how

Figure 16. The proof of concept's transaction view
Trad, 2015a; Trad, 2015b.

Figure 17. The proof of concept's layers view
Trad, 2015a; Trad, 2015b.

- to integrate these various data standards in the BTP.
3. An enterprise data service bus and enterprise application integration concept must be defined for the BTP. That would glue the various data sources of the business environment.
4. The meta-model and the corresponding “1:1” mapping approach can be used to manage an agile business transformation process (OASIS, 2014).
5. Unbundling through the use of business data services makes decision making well integrated in the context of a system that applies a holistic approach (Daellenbach, McNickle, & Dye, 2012).
6. The data services and data building blocks must unify the implementation and usage of data models.
7. Define the data architecture and modelling concept’s default critical success factors.
8. Implement an Extract, Transform and Load (ETL) process to access data from various locations to enable their unification and normalization.
9. Data transformation models need a meta-model to show the relationships between various types of data models and data sources.
10. Define a data normalization and interoperability paradigm that must be based on various standards.
11. Define a business process and a data architecture and modelling integration paradigm to enhance the business environment’s knowledge.
12. Develop an agile Model View Controller (MVC) pattern that is dynamically created for each business transaction. This MVC uses a data building block and its instance
13. Define the architecture development method’s integration with the proposed concept where the data building and solution blocks are the basic artefacts that circulate through the architecture development method.
14. Define business architecture integration paradigm that is needed to manage the implementation of the data building blocks (Trad & Kalpić, 2014b; The Open Group, 2014a).
15. Define conceptual views that can be built to simplify the application of the data architecture and modelling concept. Such views can also be used to simplify the enterprise’s data-model that links various data sources.

16. Create basic class diagrams for the data architecture and modelling concept(s) to be the central artefact that is defined in the initial phase and then calibrated in all other phases.
17. Define the usage of business transactions' data models in various class diagrams.

CONCLUSION

This is another chapter in a long series of articles (and chapters) related to the *Environment's* research framework, which is based on action research mixed method and is mainly motivated by high failure rates in business transformation projects (Wes, 2001). The proposed *Environment's* data architecture and modelling concept are result of a research and prototype development process. The requirement is to present the needed data architecture and modelling skills for a BTP's data concept that are needed to finalize the implementation phase of a BTP (The Open Group, 2014d).

FUTURE RESEARCH DIRECTIONS

The *Environment* future research will focus on a neural network based decision making module, which use a micro services concept.

KEY TERMS AND DEFINITIONS

Business Engineering: The development and implementation of business solutions using business models to business processes and organizational structure.

CSFs: Can be used to manage the statuses and gaps in various project plans and gives the Projects the capacity to proactively and automatically recognize erroneous building blocks and to just-in-time reschedule the Project plan(s).

Data Modelling: The process of developing data models for the business transformation process.

Enterprise Data Architecture: A data strategy that defines the objectives of the business transformation process's data collection management.

Environment: This research's framework.

Manager: Business Transformation Manager.

Contemporary Leadership Development in Kazakhstan

INTRODUCTION

Since the independence of Kazakhstan, 25 years ago, universities in the country have developed the system of educating and training managers and leaders for all spheres of the economy. Obviously the world-wide processes such, as globalization, integration, information technologies in higher education as well have their impact on the formation of leadership. As in many other countries in order to educate new managers and leaders, traditionally western models of human resource development were translated and adopted. This article is the continuation of the series of social-psychological researches in the Republic of Kazakhstan (RK). The co-authors began their collaboration in spring semesters of 2009 and 2010, when Dr. Tazhina was undergoing an internship at the Columbia University and together with Dr. Parker developed a joint international research project. Later, in 2012, Dr. Ivashov joined the research when he had internship at the NYU.

BACKGROUND

The Traditional Culture of Kazakhstan and Contemporaneousness/Globalization

Traditional Kazakh culture has historically been determined by the nomadic lifestyle and harsh

living conditions of this vast territory and became a regulatory mechanism for daily life. Clan membership, a clear age hierarchy and inter-familial relationships were a priority. Elders were at the top of the hierarchy and the family was and still is in charge of resolving social and psychological conflicts. (Masanov, 1998). Later Akshalova (2002) clarified, that “from outset, it should be asserted that within the Kazakhstani culture, there is respect to elders and seniors and hence, all the more, father leadership should be encouraged and practiced in small business management. After all, it is a benevolent leadership style that benefits all parties concerned – the leaders, the people and the organizations”.

For this reason, from the point of view of the identity formation and managerial education, it is important to consider the impact of globalization and a joint conflict between western mind-set and traditional values (Tazhina, 2010). The latter and a number of other social phenomena led to risen demand for applied psychology, which takes form of social-psychological training of skills such as leadership, effective communication, motivation, etc.

While individual leadership is important, the context of the organization can enhance or inhibit the leadership of its members. Dorfman and House (2004) report that at the first GLOBE research conference in 1994, there was a consensus of the 54 researchers from 38 countries (of which Kazakhstan was one) about a definition of

DOI: 10.4018/978-1-5225-2255-3.ch488

organizational leadership. “the ability of an individual to influence, motivate, and enable others to contribute toward the effectiveness and success of the organizations of which they are members” (p. 56). GLOBE is international project, which is aimed to seek answers to questions like: in what ways can community culture and organizational culture affect behavior of leaders/managers and company’s/organization’s development, commenting on the effectiveness of both?

Contemporarily, Kazakhstan is actively involved in the processes of globalization and integration. The following are just some examples of such activity: OSCE Chairmanship of the RK in 2010 and the largest international exhibition of the decade, EXPO, is to be held in the capital of Kazakhstan in 2017. In this context the necessity of studying leadership and its development in each segment of the society and economy is evident.

Leadership Issues

The American historian David McCullough (2008) emphasizes that “We need leaders and not just political leaders. We need leaders in every field, in every institution, in all kinds of situations. We need to educate our young people to be leaders” (p. 45). He asserts that “the great leadership lessons don’t change” (p. 45) and cites numerous historical figures that he considers demonstrate these fundamental qualities.

In an effort to analyze leadership itself, numerous authors and researchers have delineated types of leadership. Lojeski and Reilly (2008) begin with noting that the most “traditional view of leadership is that of a manager: one who monitors, controls, and, more importantly, rewards desired behavior and punishes undesired behavior. However, they label several other types of leaders. They note that “Charismatic leaders are people who can make the emotional connection”. (p. 124). “Transformational leadership includes four kinds of behavior: 1. Idealized influence refers to actions that demonstrate vision, values, and beliefs and creates a sense of identification with the leader among

followers. 2. Individualized consideration involves coaching and encouraging and also promoting each individual’s belief that they can be successful. 3. Inspirational motivation involves creating a clear and appealing vision and serving as a model for desired behavior. 4. Intellectual stimulation involves making the team aware of problems and bringing new ideas so that followers become engaged in finding solutions. Transformational leaders also create an emotional connection with their followers so that their behaviors contribute to followers’ sense of ownership and commitment to the team’s goals and tasks” (p. 124-125).

However, putting these types of leaders into the context of a technology rich society, context, Lojeski, & Reilly (2008) note that transactional, charismatic, and transformational views of leadership were developed before the Digital Age, when organizations and teams were likely to be collocated and more culturally homogeneous. They suggest that today’s organizations need the ambassadorial leader. “The ambassadorial leader is a boundary spanner. Like an ambassador, the leader must span geographic, cultural, and organizational boundaries and foster trusting relationships among disparate groups of people” (p. 130). Wiseman and McKeown (2010) categorize leaders as multipliers and diminishers. They explain that “some leaders make us better and smarter. They bring out our intelligence”; some “focus on their own intelligence and their resolve to be the smartest person in the room had a diminishing effect on everyone else”. Their “research showed, that most of us fall along this spectrum and have the ability to move toward the side of Multiplier” (p. 29).

Culture and Leadership

Leadership is inextricably intertwined with both national and organizational culture. Hofstede (2001) explains the relationship between national culture and leadership by suggesting that “ideas about leadership reflect the dominant culture of a country. Asking people to describe the qualities of a good leader is in fact another way of asking

them to describe their culture. “The leader is a culture hero, in the sense of a model for behavior” (p. 388). Schein (1996) notes, that “leadership is the fundamental process by which organizational cultures are formed and changed” (p. ix). However, House & Javidan ((2004) emphasize that “we are just beginning to understand how culture influences leadership and organizational processes” (p. 9). They note that “given the increasing globalization of industrial organizations and the growing interdependencies among nations, the need for a better understanding of cultural influences on leadership and organizational practices has never been greater” (p. 10).

Dorfman and House (2004) cite numerous studies that

... document the astonishing diversity of organizational practices worldwide, of which many are acceptable and considered effective in one country and ineffective in a neighboring country. (p. 52)

They also provide examples of non-western conceptualizations of leadership. However, they continue by suggesting that this is similar to “task-oriented” and “support-oriented” leadership functions in Western leadership theories.

Interesting conclusions were made by Grachev (1999) and Ardichvili & Kuchinke (2002) about the corporate practices (“as they are”) in former USSR countries, which “take marginal place in international system of coordinates in the majority of parameters of GLOBE”. Therefore, this confirms the unbalanced and frequently unpredictable form of leadership/management style inside a company in these countries when working with foreign management.

Parker (1997) adds an example of global educational practices in the technical community at 3M. She notes that the growth of business in the Asia region in the 1990’s demanded educational programs in leadership skills. A number of learning activities were developed by her in partnership with consultants in Europe and Asia to meet these needs. The objective of their partnership was to

maintain sensitivity to and balance between the Western culture of the Minnesota based company and the cultures of the Asian countries.

Emphasizing the importance of local culture, Tazhina (2010) reported “it is vital to take into account traditional culture in training of managers. Only local trainers can understand the culture and mentality of the people living in their country and provide the most effective training” (p.2).

While attention to cultural differences is important, Dorfman & House (2004) also suggest that

... there is a substantial amount of cross-national convergence of management practices, values, and beliefs. This occurs as a result of interactions among organizations engaged in cross-border trading, and wide-spread proliferation of management education programs that reflect Western assumptions, values, and practices. (p. 53)

They cite Hofstede’s studies from the early 1970’s and their replication over the decades as evidence that change in these fundamental cultural values appear to be very slow and quite resistant to convergence forces.

Issues of national culture are complicated by the superposition of the culture of the organization itself. Schein (2004) explains that

... leaders externalize their own assumptions and embed them gradually/consistently in the mission, goals, structures, and working procedures of the group. Whether we call these basic assumptions the guiding beliefs, the theories-in-use, the mental models, the basic principles, they become major elements of the emerging culture of the organization. (pp. 406-407)

However, one additional influencer over this time has been the introduction of technology at varying rates in different cultures. Schein (2004) noted that

The introduction of any new technology into an organization, or society can be seen as a culture

change problem. Occupations typically build their practices, values, and basic self-image around their underlying technology. (p. 36)

As new technology is introduced into learning and leadership additional adaptations will need to be made. Schein (1985) also noted that

We should of course recognize that many people resist new technologies because they correctly sense that their cultural assumptions are being challenged and threatened. Technological changes not only disrupt behavioral patterns but force one to change underlying assumptions. (p. 288)

This will be an essential skill for the development of leadership in any country or organization.

CURRENT PERSPECTIVES

The initial research by Parker & Tazhina (2011) looked at leadership models and career orientations in Kazakhstan based on the selection of 60 graduate students, working in various industries. The research was redirected in 2014 involving 189 graduate students. That time the selection included 117 females and 72 males aged 21 to 34, who were managers in various companies. Additionally, 60% of the students are operational level managers. 15% of the participants are middle level managers and lead HDR, marketing, supply, and customer service departments. 25% of the participants are entrepreneurs. In order to gather the data, three instruments were chosen: questionnaire on career anchors inventory, leadership style test, questionnaire on interpersonal diagnosis of personality.

Career Anchors Inventory

The career anchors inventory was developed by Edgar Schein (1985), who explains that the anchor was not only an indication of “the different things people are looking for in their career” (p. 248) but referred more strongly to “those things that

the person would not give up if forced to make a choice” (p.250). The inventory provides individuals with information about their primary areas of competence, motives, and career values. We use Russian version of inventory by Chiker (2006). Schein (1996) originally identified 5 anchors and then added 3 anchors. Chiker (p.105) divided the anchor security/stability into two and identified these as security/stability of job and security/stability of residence. The 9 career anchors are described below:

- **Technical/Functional Competence:** Like being challenged, using personal skill to meet the challenge, and becoming the expert.
- **General Managerial Competence:** Like problem-solving, dealing with other people and responsibility.
- **Autonomy/Independence:** Need to work alone, under their own rules and at their own pace.
- **Security/Stability of Job:** Seek security and stability in their jobs. They dislike personal risk, and often identify with their organization.
- **Security/Stability of Residence:** Try to stay in the same place of residence with minimum relocations and business trips. Moving for these people is unacceptable and uncomfortable.
- **Entrepreneurial Creativity:** Like to be creative, inventive and run their own businesses. They will share the workload but need ownership and are easily bored. They consider wealth a sign of success.
- **Service/Dedication to a Cause:** Driven by how they can help others.
- **Pure Challenge:** Need constant difficult problems that they can solve. They will change jobs if current one gets boring so their career can be varied.
- **Lifestyle:** Integrate life and work with focus on personal passions.

Table 1. Career anchors inventory

Career Anchor		Number of Times This Was the Dominant Anchor for a Student, %		Mean of Career Orientation	Standard Deviation
		2010 N=60	2014 N=189	2014	2014
Technical/Functional competence		1,3	1,6	5,3	0,8
General Managerial competence		21	17	6,8	0,7
Autonomy/Independence		12	7,9	6,7	1,1
Security/ Stability	of job	1,3	32	7,3	0,5
	of residence	2,6	4,8	4,4	0,7
Entrepreneurial Creativity		29	11	6,7	1,0
Service/Dedication to a cause		15	11	6,9	1,1
Pure Challenge		5,1	3,2	6,0	0,9
Lifestyle		13	11	7,1	0,5

The individual student scores for each of the 9 career anchors were calculated. The highest score indicated the preferred anchor. The scores were compiled to develop a frequency distribution for each anchor by percentage in 2010 and 2014, means and their standard deviation are given in Table 1.

Of particular interest are the extreme high and low numbers. In 2010 the two highest anchors, entrepreneurial creativity and general managerial competence might be attributed to the fact that the sample consisted of students in finance. In 2014 the majority of the students preferred the security/stability of job. This indicator is 25 times higher than the figure in 2010. This could possibly be due to the economic crisis in Kazakhstan, when the factor of employment became crucial for an individual. The figures for career anchors are 1.2-2.6 times lower compared to 2010's indicators excepting technical/functional competence and security/stability of residence. However, It might be considered if the lowest scores in 2010/2014, technical/functional competence, security/stability of residence, and pure challenge might be characteristics consistent with the national culture. Considering that even the oldest of these graduate students had lived through the shift from the dominance by the Soviet Union

to an independent Kazakhstan, to globalization/internalization being their personal best, needing these competences for a career. These findings are in sharp contrast to Schein's (1996) findings in the 1970's and 1980's in which in USA "roughly 25 percent of ... populations anchored in 'general management,' 25 percent in 'technical/functional competence,' 10 percent each in 'autonomy' and 'security' and the rest spread across the remaining anchors" (p. 81).

Leadership Questionnaire

The leadership questionnaire is based on the Blake & Mouton Leadership inventory which rates people on their concern with the task and people. Blake & Mouton developed a matrix on which the scores are plotted in order to identify one of 5 leadership behaviors.

- **Impoverished (Low Task and Low People Score):** Exerts and expects minimal effort or concern for either staff satisfaction or work targets.
- **Country Club (Low Task and High People Score):** Attentive to staff's relationships and the work culture but at the expense of production results.

- **Middle of the Road (Politician):** A compromiser who wants to maintain the status quo.
- **Authoritarian (High Task and Low People Score):** Focus on achievement. People are only a commodity used to achieve results.
- **Team Leader (High Task and High People Score):** Achieves high work performance by inspiring involvement and leading people to become dedicated to the organizations goals.

The people and task preference scores were calculated for the students that completed this inventory. A frequency percentage distribution of these styles is shown in Table 2. The preferred leadership style was authoritarian. It is constant phenomena for both measurements. Moreover, combining categories indicate that in 2010 only 11,4% of participants scored in the “high people” range compared to 39,4% who scored in the “high task” range. In 2014, the “high people” range increased up to 18,9% in contrast to the “high task” range that enlarged to 46,5% of participants.

While both the samples of 2010 and 2014 are not sufficiently large to draw conclusions, details indicated some interesting facts. Authoritarian style is the most prominent in the selection. The majority of the graduate students prefer this style and its 2010/2014 indicators are relatively similar. Further analysis has shown that number of managers with Team, Country Club and Middle of the Road styles has risen by 1.8-2.2-3.2 times respectively. The prevailing styles, Authoritarian and Middle of the Road, are relatively similar for both genders. In 2014 the number of students with Impoverished style has dropped 1.5 times compared to 2010.

Interpersonal Diagnosis of Personality

To conduct the interpersonal diagnosis of personality (IDP) amongst managers the Leary's (1957) approach was chosen, but in its Russian-language modification by Sobchik (2004). IDP was used for managers to draw their own portrait as a leader. A respondent is asked to decide whether 128 statements represent his/her Real Self.

Table 2. Leadership questionnaire frequency distribution

Leadership Style	Indicator	Frequency, %		Mean and Standard Deviation, 2014	
		2010	2014	Concern with People	Concern with the Task
Country Club	High People/Low Task	1,6	3,2	7,0±1,4	3,5±0,7
Country Club/Team	High People	3,2	3,7		
Country Club/Impoverished	Low Task	11,5	6,9		
Impoverished	Low Task/ Low People	18,0	12	2,2±0,9	3,0±1,0
Impoverished/ Authoritarian	Low People	19,7	6,7		
Authoritarian	Low People/ High Task	27,9	26	2,5 ±0,8	6,4±1,4
Team/Authoritarian	High Task	4,9	8,5		
Team	High Task/ High People	6,6	12	6,8±0,6	6,8±1,2
Middle of the Road		6,6	21	5,0±1,1	5,1±0,9

Characteristics that don't go beyond 8 points are inherent to well-balanced individuals. Characteristics that exceed 8 points indicate the accentuation of attributes, that are described by a given octant. 9-12 points imply a high severity of the behavior, even leading up to an extreme.

In order to demonstrate the main social orientations Leary (p. 214) has developed a provisional diagram/circle divided into sectors. In this circle the horizontal and vertical axes are marked with 4 orientations: dominance-submission, friendliness-hostility. In turn, these sectors are divided into 8 more particular cases. The sum of points in each orientation is converted into an index, where the vertical (dominance-submission) and horizontal (friendliness-hostility) axes are dominating. The interval between deduced indicators and center of the circle points out to the adaptability or extremity of interpersonal behavior.

Leary (p. 168) has identified the following types of interpersonal behavior. The modified titles by Sobchik (p. 122) are shown in brackets.

1. Authoritarian (imperious-leading),
2. Egoistic (independent-dominating),
3. Aggressive (straightforward-aggressive),
4. Suspicious (untrusting-skeptical),
5. Submissive (meekly-shy),
6. Dependent (dependent-obedient),
7. Friendly (cooperating-conventional),
8. Altruistic (responsibly-generous).

All styles of interpersonal behavior are present amongst participating managers, with the exception of severely prominent maladaptive variation of untrusting-skeptical style. The means of interpersonal behavior styles were calculated for each leadership style (Table 3).

It can be seen that managers with Authoritarian and Country Club leadership styles are relatively balanced in their interpersonal interactions, rather than managers with other leadership styles. Managers with Impoverished and Middle of the Road leadership styles are extremely authoritarian. And managers with Team leadership style are the most contradictory with polar extreme tendencies towards authoritarianism and altruism. Based on this information Figure 1 demonstrates the circles of interpersonal behavior for five leadership styles.

Additionally, friendliness and dominance indices were calculated as well as the prevailing type of attitude to the peers. According to Leary (p. 174), the following formulae allow deducing dominance index (vector V) and friendliness index (vector G):

- Dominance $V = (I - V) + 0,7 \times (VIII + II - VI)$
- Friendliness $G = (VII - III) + 0,7 \times (VIII + VII - II)$

A result, that has a positive or negative direction incline, reveals the prevailing tendencies. According to Sobchik (p. 128), given recipes are

Table 3. Means of interpersonal styles by Leary for each leadership style by Blake & Mouton

Leadership Style by Blake & Mouton	Interpersonal Styles by Leary							
	Authoritarian	Egoistic	Aggressive	Suspicious	Submissive	Dependent	Friendly	Altruistic
Authoritarian	8,8	7,1	6,3	5,8	5,4	6,3	7,1	7,6
Country Club	8,0	8,5	6,0	3,5	4,5	5,5	8,5	6,0
Impoverished	10,7	7,6	6,9	6,9	5,6	5,7	7,3	7,8
Middle of the Road	10,0	7,0	6,8	6,1	4,6	5,1	7,0	8,1
Team	9,1	7,6	7,2	6	6,3	7,6	8,3	10,1

Figure 1. The Leary Circles of interpersonal behavior for five leadership styles

especially informative when generalizing data for a particular group, rather than a single individual (Table 4).

For each leadership style the prevailing tendency of IDP is dominance. Dominance index surpasses the friendliness index 2.5-9.5 times. Interestingly, the highest dominance figures are observed for impoverished and team leadership styles.

Table 4. Dominance and friendliness indices in accordance with IDP methodology vs leadership styles by Blake-Mouton

Leadership Style by Blake & Mouton	Prevailing Tendencies of Interpersonal Behaviour	
	Dominance	Friendliness
Authoritarian	9,35	3,21
Country Club	9,8	2,31
Impoverished	11,89	-0,3
Team	12,27	0,3
Middle of the Road	9,87	3,97

CORRELATIONS

SPSS statistical software was used to calculate the Spearman's rho correlations between each of measured scales and other numbers of the other instrument (Table 5).

There is a significant positive correlation between MT participants and those with security/stability of job (SEJ), entrepreneurial creative (EC), and technical/functional (TF) career anchors. There are also notable positive correlations between MP participants and those with lifestyle; and negative correlations with entrepreneurial creative career anchors. The similar correlations were found out in 2010th sample.

Within significant positive correlations between interpersonal relations and career anchor categories, the highest correspondences are between dominant/aggressive/friendly interpersonal relations and general managerial competence career anchor; between competitive interpersonal relations and security/stability of job (SEJ); between altruistic interpersonal relations and entrepreneurial creative career anchors.

Table 5. Correlations

	MP	MT	Authoritarian	Egoistic	Aggressive	Suspicious	Submissive	Dependent	Friendly	Altruistic
TF		.356*	.391*							
GM			.615**	.459*	.455**		.307**		.510**	
AU								-.489*		
SEJ		.410**		.591*						
SER								.391*		
EC	-.351*	.396**	.440**							.409**
SV										
PC					.387*					
LS	.301**						.309**		.483*	.375*

TF: Technical/Functional competence

GM: General Managerial competence

AU: Autonomy/Independence

SEJ: Security/Stability of job

SER: Security/Stability of residence

EC: Entrepreneurial Creativity

SV: Service/Dedication to a cause

PC: Pure Challenge

LS: Lifestyle

MP: People oriented management style

MT: Task oriented management style

*Correlation is significant at the.05 level

**Correlation is significant at the.01 level

It is remarkable that dependent interpersonal relations correlate negatively with autonomy/independence, and positively with security/stability of residence career anchors.

FUTURE RESEARCH DIRECTIONS

The obtained data about managers of different levels complement the information on leadership in Kazakhstan. Tazhina (2010) provides specific recommendations for the future within the area of applied psychology and leadership. She notes that “While Kazakhstan has the necessary resources; it needs fundamental development in psychological research”. Also Low (2013) examined leadership in relation to small business leadership and management in Kazakhstan. “The business owners/leaders or entrepreneurs are to extend their personal influence so that there can be positive effects with results attained for organizations. In

fact, there have been very few studies on leadership in small businesses in the Republic of Kazakhstan; hence the need for such study” (p.225).

Technology and e-learning will certainly be a part of future impacting leadership practice and possibilities. Fedoroff (2012) comments that “today, countries all over the world aspire to have high-skill, high-value economies, to become ‘knowledge societies’ and ‘knowledge economies.’ The extraordinary value of knowledge is, of course, that there are no limits to its growth or the value it can generate. Going beyond local benefit, it is increasingly important to create a global knowledge society” (p.503).

Tazhina & Parker (2013) surveyed the role of distance learning technologies in preparing global leaders in Kazakhstan. They noted some characteristics unique to the country, but also some aspects shared with other countries globally. “Kazakhstan is approaching its future with bold steps in the use of technology to educate its

workforce. The model used at UIB for distributing the knowledge of its faculty from the campus in Almaty to 5 regional centers around the country may well become a model for other universities. And the impact of the skills learned in a distance learning environment will influence the future of the nation and its workforce” (p.480).

Raising leaders in Kazakhstan is the issue of a day. Thus, there was held the International Scientific-Practical Conference for young scholars “Intellectual Leadership: New Stage in Development of Kazakhstan” by the Academy of Public Administration in February of 2016. Researchers in their early career, PhD and master students have discussed how to develop creative activity, principles of the professional state, priorities of the new economic and foreign policy of Kazakhstan in the context of globalization during breakout sessions.

CONCLUSION

This article is the continuation of series on social-psychological research in Kazakhstan. The obtained data is of a great interest and partially agrees with the existing few researches on leadership in Kazakhstan. Low (p.226) identified father leadership in Kazakhstan. “It can be said that Kazakhstani people tend to expect that employers provide transportation and this is a standard practice in many banks and most manufacturing companies. The father (leader) can be strict (task-oriented, and in this way, things get done) and may discipline yet he is caring (relationship-based)”.

In this research young graduate students, who were taught about western leadership theories, using the latest information technologies, and working as managers of various levels, still tend to choose traditional leadership values. This is evident when team leaders can simultaneously be highly dominant/authoritarian and altruistic. As Low (p.226) stated “as the country develops,

people will acquire more skills and further education, and with adequate numbers of skilled business executives, more will be exposed to individualism and the *laissez-faire* style. Nonetheless,...father leadership, coupled with concern for the staff's welfare, can in a way, be seen as a benevolent form of leadership; and that is gaining currency especially among the more educated Kazakhstanis”.

Ardichvili & Kuchinke (2002) compared leadership styles and cultural values in their cross-cultural study of over 4,000 managerial and non-managerial employees in several countries including Kazakhstan. “Any attempts to develop leadership training programs ..., or to conduct organization development interventions based on Western ... theories, should be tailored to each country's specificity, and the ... Republics should not be treated as homogeneous in their management and work cultures.

KEY TERMS AND DEFINITIONS

Career Anchor: “A person’s career anchor is his or her self-concept consisting of 1) self-perceived talents and abilities, 2) basic values, and most important, 3) the evolved sense of motives and needs as they pertain to the career”. (Schein, 1996, p. 80).

Cultural Dimensions: The characteristics of a national culture usually associated with those dimensions defined in Hofstede’s work.

Culture: The shared attitudes, beliefs, practices and values that characterize a group.

Leadership: The ability of an individual or group to promote the ideas and to guide the vision of a group or organization.

National Culture: The culture associated with a geographical/political region and its inhabitants.

Organizational Culture: The culture attributed to an organization and usually associated with the values of the founders and leaders.

Technology: The application of scientific advances usually involving electronic advances.

M

Empirical Verification of the Performance Measurement System

Aleksander Janeš

University of Primorska, Slovenia

INTRODUCTION

Ebm-papst Group is Germany's most sustainable company which has a global sales network and is worldwide innovation leader in electric fans and motors. The Ydria Motors LL Company (YM) is a member of the ebm-papst group and is organized as a competence center that produces and develops machines, appliances and AC and EC electric motors and exports as much as 98% of its production. The company is wholly owned by the ebm-papst group (Ydria Motors, 2015).

Practical experiences with the Performance Measurement System (PMS) show that it is difficult to determine transparent relations between the different perspectives. However, the implemented PMS doesn't enable the identification of all information on the relations (i.e. causalities) between process Key Performance Indicators (KPIs). In this manner company doesn't have transparent evaluation of resource inputs in efficiency of the implemented model in the management system (Janeš & Dolinšek, 2010; Waruhiu, 2014). In the light of its development, the company has to resolve the issues to outline its future organic growth. Thus, the YM Company has already faced the challenge of setting the KPIs, which are the central theme of represented research.

Primarily, the represented research is focused on the layout of the balanced scorecard (BSC) i.e. it's causal relations, using qualitative and quantitative methods. In this case study, the company's business performance sustainability understanding, which is based on comprehensive data tests and semi-structured interviews with managers, contributed to the selection of Engle-Granger

two-step method for assessment of the error correction mechanism between the KPIs.

BACKGROUND

One of the main purposes of implementing PMS is to communicate strategy throughout the organization. Among the number of PMS approaches, a dominant position was achieved by Kaplan and Norton's BSC; it has emerged as a new synthesis between the traditional financial-accounting system and efforts to achieve long-term competitive ability. The BSC system considers the traditional financial KPIs as well as leading KPIs of future performance. In this way, it provides key information about the activities of managers. The BSC is a PMS theorized by Kaplan and Norton which was first created as a performance measurement tool, which has later evolved into a PMS, and has subsequently become a comprehensive strategic management system (Barnabè, 2011; Janeš, 2014).

Measurement of the organization's performance represents a good practice and is an integral part of the organization's management in the accomplishment of its strategies and objectives. The BSC and associated KPIs are treated in practice as a process that supports the reviewing and changes of the measurement system in relation to changes in the business environment of the organization.

Given the framework of the strategy map, which consists of four perspectives, and within them a large number of related strategic objectives, the added value of the business processes is manifested in the form of chains of cause-effect relations ranging from nonfinancial and quantifiable KPIs in the

learning and growth perspective via processes and customers to a finance perspective (Waruhiu, 2014; Kaplan, 2012, p. 543). Cause-effect relations can be understood as a set of hypotheses that are taken to meet the strategic objectives. A strategy map is a diagram that describes how an organization creates value by connecting strategic objectives that are in explicit cause-effect relations with each.

Approach of setting practical objectives is being performed through a series of approximations. Keeping the maximization of the rate of return as the stakeholder's long term value, companies usually develop a number of subsidiary objectives which contribute in different ways to improvement in the return and which are also measurable in business practice. A company which meets high performance in most of its objectives will enhance its long-term rate of return. But it cannot be proved that the result will be a maximum possible overall return. Namely the problem of reconciling claims of conflicting objectives is common across all sectors. In business practice company's objectives are what the company wants from its key stakeholders. Essential nature of company objectives makes a logical connection between what stakeholders want from a company, i.e. "strategic factors", and what the company wants from its stakeholders, i.e. "organization objectives". Both sides together provide real strategy framework. For example one of the stakeholder groups represents customers from which company wants to achieve profitable revenue. If an objective is an expression of what an organization wants from a key stakeholder, it must involve behavior by a stakeholder and, a desired behavioral outcome (Kenny, 2012, pp. 42-43). Once developed, strategic objectives will shape an organization's strategies effectively, leading to sustainable success. It's important to remember that targets on organization objectives shape strategies; they also provide a means of assessing the effectiveness of those strategies. Namely, without clear and quantified objectives, any strategy can be set (Kenny, 2012).

One of the main areas that both the relevant literature and Kaplan and Norton themselves

identified as being critical, is related to the identification and assessment of causal relations which are essential within the BSC (Barnabè, 2011; Barnabè & Busco, 2012; Kaplan, 2012; Nørreklit, 2000; Waruhiu, 2014, p. 119). In this context, the causal relations have been in the center of survey interest, because they are providing better relations model between the four BSC perspectives (Bukh & Malmi, 2005, p. 96).

CASE DESCRIPTION AND DISCUSSION

Methodology

The research project of empirical verification of the PMS was performed as a single case study of modeling the BSC system for a manufacturing company and founded on the complementary use of quantitative and qualitative methods (Gummeson, 2000, p. 88). For this purpose, were obtained and used KPIs that were already monitored by the company on a monthly basis and ranges from 2005M01 to 2011M12. Since the exact legalities between the observed KPIs were not known, the information contained in the time series of observed KPIs were expressly applied. Based on the selected Engle-Granger two-step method, a framework for the layout of the BSC including EVIEWS statistical software was defined (Engle & Granger, 1987). The central part of the case study is the part in which the empirical evaluation of the BSC's layout with the Engle-Granger two-step method was performed. Before starting with the Error Correction Model (ECM) modeling, several basic statistic tests of the KPIs' time series, i.e. stationarity and cointegration, were performed in order to exclude the possibility of false regression (Engle & Granger, 1987; Granger, 2004; Hassouneh, Serra, & Bojnec, 2015).

The main objective of the research aimed at developing a quantitative approach that would be complementary with a qualitative approach of the BSC layout. For this purpose a single equation

ECM was developed with the Engle–Granger (1987) two-step method. In the first step, the cointegration was evaluated. The linear combination of observed KPIs represents a co-integration vector that could be stationary. If the cointegrating vector is unique, then the ordinary least squares (LS) method can be applied to estimate the relation among KPIs. In this case, the residuals from LS regression equation can be used in place of the error correction term (u_{t-i}) to proceed with the estimation of the short-term dynamic model. To this end, the initial model of KPIs was set; the regression was calculated by the LS method and the residual values of the potential co-integrating vector were saved. The residual values were tested for stationarity, which is needed for the stability of the final model but it also confirms co-integration relations between the KPIs.

In the second step, the ECMs were set up using the seasonal differences and different time lags of KPIs and residuals. According to Engle and Granger (1987), when the variables are cointegrated, there must be an error correction mechanism that describes the short-run dynamics of the cointegrated variables towards their long-run equilibrium values. In the presentation of the ECMs (Table 1), u_{t-i} is a lagged error correction term that measures the speed of adjustment to long-run equilibrium. In order to restore equilibrium, the sign of the coefficient of the, u_{t-i} is expected to be negative (Engle & Granger, 1987; Janeš & Faganel, 2013).

Application of the Engle-Granger two-step method on the KPIs was performed with the ECM approach and short and long term effects between them were estimated.

A strategic map of the YM Company that contains the causal relations between the KPIs has been set and confirmed with the executive management. The method of semi-structured interviews was supplemented with the participation and observation of the researcher (Angrosino & Mays de Pérez, 2000; Bititci, Mendibil, Nudurupati, Garengo, & Turner, 2006; Bukh & Malmi, 2005; Gosselin, 2005; Janeš, 2014; Kaplan, 2012).

Design of the Strategic Map

The method of semi-structured interviews in the form of workshops has enabled the qualitative analysis and modeling of the layout of the BSC. It was designed after a preliminary representation of the BSC concept to the executive management and with the use of prepared open questions, which directed the workshops. The strategic map has made it possible for the consensus between the executive managers and communication of chosen strategy in the range of “a story on one page”.

The cause-effect relations that are of interest for modeling and those that were modeled with the Engle-Granger method are clearly outlined in the strategic map (Figure 1). The latter are represented by the capital letters B, C, D and F. Relations that are not marked are those that we could not take into account due to different frequency of measurement.

The BSC model was designed with the involvement and consensus of the executive management in eight workshops, in which the following conclusions were reached:

- With the introduction of the BSC concept to the top management, the management has become familiar with the process of BSC modeling. The ultimate goal of the workshops was a designed BSC system, in which cause-effect relations were supported by an Engle-Granger method.
- With regard to the content of a destination statement, consensus was achieved, consisting of a single page and divided into four parts: financial expectations and expectations of the owner, strategic partnerships, business processes and sustainable development of the company. The destination statement, in a condensed form, represents a desired state of the company in the next three years from the viewpoint of executive management.
- Strategic themes represent decomposition of the overall strategy, because they con-

Figure 1. YM strategic map

tain essential parts, they define business processes that add value for stakeholders and enable the classification of strategic objectives (Figure 1).

$$\Delta MPROF_t = \alpha_0 + \sum_{i=1}^n \alpha_1 \Delta ABSE_{t-i} + \sum_{i=1}^n \alpha_2 \Delta ACCW_{t-i} + \sum_{i=1}^n \alpha_3 \Delta LPROD_{t-i} + \sum_{i=1}^n \alpha_4 \Delta YMPPM_{t-i} + \alpha_5 u_{t-i} + \varepsilon_t \quad (1)$$

Modeling of the Strategic Map

Due to the limited space, only some of the findings from the ECM analysis are represented. The use of the ECM approach can be seen on the case of the monthly profit (MPROF). From the Equation 1 it is evident that MPROF of the company depends only on internal KPIs. This is because the YM Company acts as a contract manufacturer. The production price of products is based on costs and is determined by the YM Company, whereas the market price of products is determined by the owner.

Since the monthly data were available, 12th time lag of the KPI's was included in the initial model- Equation 1.

The structure of the lags was evaluated with the criteria for determining the order of time lags, as are autocorrelation function, Q-statistics and correlograms. By testing various time lags of KPIs on the right side of the equation and the reduction of autocorrelation, respectively, monitoring the Durbin-Watson statistics, the final ECM was identified. The results from Table 1 can be interpreted as follows: the optimization of the MPROF is influenced by the MPROF from previous periods, absenteeism (ABSE), accidents at work (ACCW), labor productivity (LPROD), and the reduced parts per million (YMPPM). Short-term changes in the independent KPIs disrupt a balance between indicators of the ECM and cause the change of

Table 1. Comparison between the ECMs

Dependent Indicators	Monthly Profit (MPROF)*	Total Expenses (TEXP)	Earnings before Taxes (EBT)	Total Sales (TSAL)*	Return on Assets (ROA)
u_{t-i}	-0.995906	-1.004654	-1.000248	-0.983107	-0.999435
R ²	0.995342	0.998118	0.998787	0.973861	0.999990
Adj.R ²	0.994913	0.997945	0.998693	0.971824	0.999990
Akaike	17.08468	16.23047	15.60983	13.23195	-5.422925
Schwarz	17.31619	16.45181	15.81240	13.43452	-5.249295
Hannan-Quinn	17.17774	16.31858	15.69126	13.31338	-5.353127
Durbin-Watson	2.190392	2.055059	2.171403	2.350735	2.130595
Johansen test (sig.0.05)	1cointeg.eq.	1cointeg.eq.	1cointeg.eq.	2cointeg.eq.	3cointeg.eq.

Janež, 2012.

Note: The least squares method is used. The data sample ranges from 2005M01 to 2011M12. In analyses, the following KPIs were used: ABSE, ACCW, cost of net-material (CNM), earnings before taxes (EBT), education (EDUC), innovation (INNO), LPROD, MPROF, return on assets (ROA), total expenses (TEXP), total sales (TSAL) and YMPPM. * Asterisk means that there is a dependent indicator on the right side of the equation.

indicators to be corrected in the next period. The error correction mechanism of the MPROF in the next period again tends to long-term equilibrium.

The ECM result represented in Table 1 confirms the presence of an error correction mechanism, which indicates a relatively stable model of short-term dynamics of the factors that affect the MPROF. The final ECM for the MPROF reflects Granger's causality caused by the independent KPIs.

All the final ECM models from Table 1 were designed with KPIs according to the labeled causal relations between KPIs that are represented in Figure 1. From the results shown in Table 1, it is evident that all u_{t-i} have an expected negative sign.

From a comparison of the results of all models, is seen a high adjusted coefficient of determination (Adj. R²), which affects the bias reduction in the estimated co-integrated vector. In addition, the Durbin-Watson statistics, which in all cases have a value of about two, means that the impact of autocorrelation was significantly reduced.

Moreover, in all ECMs there are minimum values of Akaike, Schwarz and Hannan-Quinn

criteria, which confirm the suitability of selected lags in the models.

The assessment and identification of the ECMs was performed using the Engle-Granger method based on a unique cointegration equation (Johansen's cointegration test in Table 1).

A number of ECM residuals tests regarding autocorrelation were undertaken; Q-stat and LM tests have shown the presence of some autocorrelation, but without significant influence on the final ECM models.

Tests for the presence of residual heteroscedasticity showed that it is mainly present in the ECM of TSAL. In other models, there is no heteroscedasticity or it is present to a non-significant extent.

Chow's test of coefficients stability showed that from 2009 to 2010, when Slovenia was already in the economic crisis (Verbič & Črnigoj, 2014), the coefficients of equations were stable. In the case of a ROA model, the test showed the existence of a breakpoint and in the case of TEXP the model stability was not confirmed for the 2010. For this reason, Quandt-Andrew's test of stability was performed, which has shown the existence of a breakpoint in model for TEXP. Therefore, the

Figure 2. Static-deterministic forecast simulation for one period ahead

Source: Adapted from Janeš, 2012.

Chow Forecast Test was conducted which showed the stability of the coefficients of the indicators in the period from 2009 to 2010, with the exception of the model of EBT and in the case of a TEXP model, stability was confirmed only for the period between 2006 and 2009. In the end, the recursive estimation of coefficients was carried out. The latter showed that in all cases ECMs coefficients are stable in the period from 2008 to 2010.

Based on the results of all performed tests, was ascertained the presence of a certain proportion of autocorrelation, heteroscedasticity and some instability in the coefficients of the individual models. However, based on the number of performed tests and their statistical significance, the ECM models were suitable for the merger in a linear forecasting simulation model.

Identification of the Linear Model

The identity of the linear model is that for which it is expected to prevail in the application in real cases. ECM equations are derived from statistical estimation procedures, while the identity is built on the basis of grounded relations between KPIs. With testing the forecasting capability the criteria of model adequacy are fulfilled as the forecasts are compared to the actual values of the KPI's time series. The linear model describes the linear relations between stakeholder's long-term value-MPROF KPI and the final ECMs (Equation 2).

$$MPROF = TEXP + EBT + TSAL + ROA \quad (2)$$

In order to test the linear model of MPROF, a static-deterministic forecast simulation for one period ahead was performed. In the case of static-deterministic forecast simulation the model in the selected period was relatively reliable with some minor to medium deviations. Therefore, it can be asserted that the linear model of MPROF is relatively suitable for short-term forecasts with a static-deterministic simulation. That was also confirmed with the Theil's coefficient of inequality, which represents the assessment of the

forecasting capacity and indicates the adequacy of the models. The results of the test are the following: for the MPROF it is equal to 0.108529, for the TEXP it is equal to 0.060058, for the EBT it is equal to 0.257273, for the TSAL it is equal to 0.077669 and for the ROA it is equal to 0.108529. It was noticed that in the long run, in 2011, the model no longer follows the actual values, which is a consequence of a relatively short period of data sample; therefore the simulation is no longer adapted to the actual values (Figure 2).

To fulfill the purpose of empirical verification of the BSC system, a long-term stochastic-dynamic forecast simulation was also performed. Based on the simulation results, it was found that the long-term stochastic-dynamic forecast simulation model for many periods in advance is not adequate. In addition, the Theil's coefficient of inequality test is the following: for the MPROF it is equal to 0.236994 for TEXP is equal to 0.091690, for the EBT is equal to 0.257173, for the TSAL it is equal to 0.544545 and for the ROA it is equal to 0.832250. A relatively large standard error, which is present in most of the observed indicators, is certainly due to the proportion of heteroscedasticity, but they do not affect the stability of coefficients in ECMs (Figure 3).

The comparison between the static-deterministic and stochastic-dynamic forecast simulations showed that the first simulation is more adequate. Econometric models that use time series are the most reliable for short-term forecasts, but this does not affect their validity (Pindyck & Rubinfeld, 1998; Janeš, 2014). By setting up the final ECMs for the financial KPIs (Table 1) and the static-deterministic/stochastic-dynamic forecast simulation (Equation 2), the layout of the BSC was empirically verified and confirmed.

SOLUTIONS AND RECOMMENDATIONS

One of the major challenges for competitiveness and the opportunity to improve business processes was the transition to the new SAP ERP business

Figure 3. Stochastic-dynamic forecast simulation for many periods in advance

Source: Adapted from Janeš, 2012.

M

information system in 2012. For the SAP ERP project it is a necessity to have well defined processes and their respective KPIs. Because well-defined processes represent the background for descriptions of “the rules” with which SAP’s programmers can efficiently and effectively write programming code for modules of the whole information system.

In order to support these endeavors, the project of empirical verification of the PMS has been started in about the same period in 2011.

The company’s executive management was interested in the project because the establishment of a BSC begins with an overview of the strategy and is not based on actual outputs of business processes (Kaplan & Norton, 2004; Kaplan, 2012; Thakkar, Deshmukh, Gupta, & Shankar, 2007). Therefore, KPIs should be directly related to the strategy of the organization; it is mandatory to choose them on the basis of the strategic objectives of the organization (Hoque & Chia, 2012). The BSC and associated KPIs are treated in practice as a process that supports the reviewing and changes of the PMS in relation to changes in the business environment of the organization, and its success depends on the compliance with the qualitative and quantitative perspectives. It is necessary to clarify why, what and how often is needed to measure before the decision of how to measure. Managers were first asked about what they want to achieve, what their objectives are and how they can describe them. Historically, the processes in the YM Company were investigated mainly as qualitative. Previous research of business processes and PMSs was predominantly performed with the data within a short period of time. They are not taking into account that some activities have an immediate impact, while the impact of some others is manifested only after a certain time (Banker, Potter & Srinivasan, 2000; Faganel & Trnavčević, 2012; Kasperskaya & Tayles, 2013; Thakkar et al., 2007). It is important to emphasize that longitudinal and dynamic research for developing theories in this area is very rare (Janeš, 2013; Kaplan, 2012; Waruhiu, 2014).

Kaplan and Norton’s BSC provide a comprehensive framework that translates the strategy objectives of the organization into a coherent set of KPIs. As a rule, the KPIs are determined based on previous experience and through regular reviews. Where appropriate, an expanded range of KPIs may be included or some of them may also be phased out. With this approach, it is possible to find measurable perspectives of the current business processes, because the selected KPIs are likely to be important for determining the outcome of business processes in the future.

FUTURE RESEARCH DIRECTIONS

The concept of causality in the BCS is not extensively explained and seems unclear. In particular, in emphasizing that improvements in one area of the BSC lead to improvements in others, Kaplan (2009, 2012) and Kaplan and Norton (2004), have identified complex causal relations, subsequently connecting many KPIs across the four perspectives (Barnabè, 2011; Waruhiu, 2014, pp. 119-120).

The analysis of many qualitative and quantitative research studies about the implementation of KPIs, performed globally, showed the generally favorable influence of the KPI’s on the fulfillment of the sustainable strategy. Specifically, a recent trend in the performance evaluation of companies is the increasing emphasis on intangible measures and non-financial perspectives (Chareonsuk & Chansa-ngavej, 2010; Jerman, Kavčič, & Korošec, 2012; Kaplan, 2012). The completion of qualitative research with statistical tools holds great potential. In cases where companies have time series data related to their KPIs with which to validate the causal relations from the strategy map, proper statistical procedures could be applied (Bukh & Malmi, 2005; Janeš, 2013, 2014; Kaplan, 2012). However, it must be emphasized that the generalization of research findings had to be limited to only one manufacturing company. Based on the results it is recommended that further research is oriented on expanding the BSC on other entities within the ebm-papst group as well as at the top

strategic management level and to use the causal relations to forecast the future trajectory of the strategy (Kaplan, 2012). In addition, the use of nonlinear methods for the ECM modeling should also be considered. Further research in the form of additional case studies, i.e. companies from all sectors that operate independently on the markets, is definitely recommended, because the key issue about the KPIs causal relations is whether they really contribute to the benefits of the business processes exploitation and strategy fulfillment (Bukh & Malmi, 2005; Janeš, 2013; Janeš & Faganel, 2013).

CONCLUSION

One of the main areas that the relevant literature, BSC users, and Kaplan and Norton identified as being critical issues to be further developed is related to the assessment of causal relations which are essential within the BSC. The literature and practice has identified the necessity to further define the concept of causality within the layout of the BSC, in the direction of relying on specific quantitative tools needed to convert the BSC into a mathematical model (Janeš, 2012, 2014; Janeš & Faganel, 2013; Kaplan, 2012).

In this case study, the company's business performance sustainability understanding contributed to the selection of Engle-Granger two-step method for the assessment of the error correction mechanism between the KPIs. Therefore, based on the reviewed literature on ECM, the main characteristics of this approach have been depicted and, in particular, the potential of using ECM for exploring the concept of causality in BSC have been stressed. Consequently, a deeper understanding about the relations between financial and non-financial KPIs has been gained (Barnabè & Busco, 2012).

In addition, the data reveal an impact of global crisis on the company captured in a way that ap-

pears as not being substantial. A key finding in this regard is that the development of the BSC, supported by the Engle-Granger method, makes a substantial contribution to the causality explanation of the BSC system.

KEY TERMS AND DEFINITIONS

AC and EC Motors: Alternating Current motors and Electronically Commutated motors.

BSC: BSC is a managerial tool of four perspectives, which focuses attention of management on only a few most important KPIs.

Cointegration: Means that series have a common trend. If a pair of variables is cointegrated then it is likely that, they have a common factor and that one of the variables causes the other variable.

Error Correction Model: When the KPIs are cointegrated, there must be an ECM that describes the short run dynamics of the cointegrated variables towards their long run equilibrium values.

Error Correction Term: Measures the speed of adjustment to long run equilibrium between the KPIs.

KPIs: The most important performance indicators of PMS by which can be followed progress towards achievement of strategic goals.

SAP ERP: Systems, Applications, and Products in Data Processing for Enterprise Resource Planning.

Lack of Characteristics Management Causing Biggest Projects Failure

Loredana Arana

University of Phoenix, USA

INTRODUCTION

You might have the right amount of resources, the right amount of skill sets, the right amount of money and the perfect project plan. However, what you thought it was going to be an easy project will turn into a total disaster if you are not managing your resources characteristics or personalities. Once you are aware you have a problem, you now have to switch to damage control mode and waste valuable time, instead of concentrating on the core objectives of your project. This is byproduct of not properly assessing your resources correctly. Projects in themselves are complicated to manage; so dealing with difficult people can add more stress and create barriers that can hinder the progress. I don't think your resources plan on giving you a hard time, but like the old adage says, *the path to a project nightmare is littered with good intentions*. Project success is not only about balancing the triple constraints (cost, time and scope); it is also about controlling all the unknowns, including your resources. A team is only established when everyone pulls together and focuses on the project objectives. Your role as a project manager is key to insuring successful outcomes. A poor project manager fails to bring out the best in his team, but a good one can produce a winning combination, even with some individuals that may perhaps seem to lack ability to do so. Leadership is a critical and essential component for any project management team. To better understand the impact of project

manager, it is helpful to consider the following definitions of project manager:

- A project manager is usually a person who is responsible to run a project from the beginning to the end. It includes organization, implementation and control of their resources including people. (Techpedia, 2013).
- Project managers need to be leaders which is the process of influencing others to understand and agree about what needs to be done and how it can be done effectively, and the process of facilitating individual and collective efforts to accomplish shared objectives (Yukl, 2002).

You need to lead which involves the ability to influence people to take actions toward completing a goal or project. Projects contain a number of components with the main three being scope, cost, and time. For the project team to effectively meet scope, cost, and time goals, one must appreciate the impact of positive leadership. It is up to the project manager to manage issues related to scope, cost, and time, as well as to lead the team to successful completion of these goals and the project as a whole. A project manager manages their project staff by developing a positive environment.

We are all very familiar with the term "lead by example". Team members may already have negative characteristics, but if the leader displays

negative traits, other team members will follow to parallel behavior as the leader. However, these types of project manager that don't lead by example introduce a whole other issues and motivational scheme in which I am not addressing in this chapter. Any individual who forms part of a team will also make a decision to commit to the team's goals; this is why they need to be sure they understand the goals. Teams normally are complicated, it is helpful for the members to ask questions, clarify any misunderstanding and get to know their project manager.

BACKGROUND

Company survival depends on how well they adapt to changing technologies, diversity of their workforce and market situation. So it is no wonder that project management is the key to guide the company in the right direction. A great deal is being written about project management addressing things like budget, time and scope, but not a lot of emphasis on how to handle resource and their characteristics. The success of any project is not only attained by following a project methodology but by adhering to and effectively using the tools and resources available to you. Past experiences have shown that diverse resources can dramatically impact cost management as well as the overall timeline. It is important to recognize resource aspects that can cause disruptions in a project and how to mitigate and manage them more effectively to reach desired outcomes. Human resources can have a negative impact to projects. Project manager need to be prepared to put challenges on permanent lockdown. When looking back on previous unsuccessful projects, it was not the methodology that was deficient but in the way that the group came together as a team. It is also critical to analyze the different personality types and how they can influence the outcomes. Early analysis and observation of each personality involved can help to isolate potential pitfalls and help to address the issues immediately. It is often

better to deal with potential problems at the start that could delay timelines, and make the necessary adjustments for the betterments of the individual, team and the project.

M

PROJECT MANAGER COMMON MISTAKE STORIES

As it is, project managers are faced with great deal of pressure from tight timeline and budget constrains. So to put more pressure they now have to deal with the dilemma of working with team members that don't even report directly to them. How can you hold them accountable for not following through with their work? We have been told that as a project manager it is normal to go through conflict and friction with your team while it is undergoing a self-adjustment phase. Although this is a normal process, it's important as a project manager to analyze each personality and make sure they don't disrupt the project. We are responsible as project managers to smooth the progress of creating conformity within our project team in multiple ways. How will you make your team members accountable for completing task if they don't get along with you or any of the other team members? You might be thinking, "Do I need to polish up on my babysitting skills?" The answer is yes you do! In my vast experience as a project manager, I have encountered team members showing bad behavior, which make them hard to manage at times. So what are basic babysitting skills? It is managing behavior problems and understanding the psychology of how different personalities types function

A big issue is project managers that are indecisive, they keep changing their mind, and they like to move the team in new directions all the time. They are reacting to everything that is received and adjusting to new feedback, while changing directions at the drop of a hat. These are project managers which think they have everything under control by doing these unpredictable moves, can only damage team productivity and hamper moral.

This in turn will only drive the team to bad behavior as method of survival. Project managers should not take side or side with complainers, if they do; they automatically join the drama club. This club will be drawn you into endless and worthless arguments that will take you away from your real focus, your project. They want to demolish your project, hinder any progress made, or devour your funds, thus prolonging your timeline and converting your project scope into what is commonly referred to project scope creep.

ESCAPING PROJECT CATAclysms

Project Manager Utmost Common Oversights

Many reference materials and experienced project managers can tell you that there will be occurrences with your project team members where they will face disagreements through out all the phases of the project, during the decisions making sessions and even after post implementation. How about when you set goals and other forces change them? One of the forces is the people around you; they usually want to sway the goals you set. Most of the time your team member may feel that they think they know what is best for project, or perhaps they have their own agenda and want to take different paths. Obviously, it is critical to curate excellent relationships with your team members. Unclear statements or expectations are another common mistake. We assume that everyone understands them and they know what is expected of them, right? Wrong! I have seen project managers over communicate with their teams with vague goals and expectations that the team can easily misinterpret.

Project managers are part of the project team so they can also be the cause of the drama. Putting a self-centered project manager in charge can discourage his or her team members especially when they try to make any recommendations. It is true that the project manager is in charge and

can make the final call, but doesn't mean that no one else can have an opinion. This can be risky proposition which can lead to serious communication barriers while undermining the very nature of teamwork which normally should include healthy dose feedback from all team members. This personality only showcases a project manager egotistical characteristic, which will develop poor team morale and less desire to participate in the project.

Obviously, mistakes will occur as it is what make us grow and became great project managers. However, if we can avoid them and be on the lookout for bad team member traits, we can concentrate on the work at hand. It is up to you to spot these team member pitfalls and deal with them quickly and in diplomatic fashion. You need to address team members' mistakes fast to minimize disruption and prevent losing control, because there is no known cure for fixing people's personalities or traits, but you will need to know how to navigate through them.

How to Overcome Your Teams Destructive Characteristics

The first steps in project management are for project manager to develop general basic skills. These skills can be acquired through education and experience. They are five skills that are considered general project manager skills very important to develop: leading, communicating, negotiating, problem solving and influencing.

Next you need to understand that it is human nature to have a tendency to classify people we come across by putting an assortment of labels. Many books written by great philosophers and writers such as Machiavelli or Plato, to name a few, have provided us a lot of information regarding people's characteristics. They all have great insights, but the truth be told that no matter how we do it we need to assess all of our interactions with people to understand their characteristics so we can manage them and control the risks. At work, we have a job to do and a role to perform.

Figure 1. General project management skills

Behaviors are influenced by what sometime it is expected of us, not the way we would like to behave. Personalities have a tendency to exercise a strong influence on work behavior (Barrick & Mount, 1993). However, people can revert back to what they want to do. No matter how exigent, confrontational, or negative the difficult person's behaviors never take it personally. You only need to know that it is best to assess these bad behaviors at the start of the project so that you can control them before they get out of hand.

By recognizing some of the difficult personalities and reacting to each effective tactics, you can develop to your advantage instead of disadvantage. Although, it said that meetings are opportunities to bring the team together and to make sure everyone is on the same page, they can be a total loss if you can't handle your difficult team members in effective ways. So, how do you handle them? It is frequently difficult if you're assigned team members that don't directly report to you. But there is still hope, you can find methods to control them and keep your project on the right track. We can take a closer look at a few of what we called our "usual suspects" types which we've all come across in multiple projects. Although you may have to do a bit of political maneuvering to get what is needed for effective collaboration from the broader organization, it is well worth the trouble.

If a person or team is too sensitive, fewer decisions will be confidently made.

Resource Detrimental Characteristics

It is true that we cannot always use cookie cutter methods with all of our resources. However, below are some of the different personality traits that I have encountered. I also like to put people on simple categories to simplify the assessment that usually helps control my resources:

- Trespasser – Entering without Permission:** These types of team members want to be in everything.. They will critique everything you say, do or even think about. You will need to learn to involve them at the beginning and make sure you can avoid intrusions during the lifecycle of your project.
- Bully – Dominating Over Everyone:** These types of team members are never happy; the only thing in their mind is to destroy your project. Everything for them is an emergency and they require a lot of attention. They like to cause turmoil, while taking everyone out in their path.
- Time Bomb – Exploding Without Notice:** These types of team members can start ca-

Figure 2. Negative personalities

tastrophe without notice. They are the ones that can bring down your communication lines with the other team members. You need to learn how to diffuse them.

- **Watchtower – Watching Every Steps You Take:** These types of team members will judge every thing you do and will find something wrong in anything you do or say. You need to find a way to engage these types and let their characteristics work to your advantages.
- **Split Personality – Double the Drama:** These types don't know what they want. They are known for lack of ownership and will go where the wind blows. You will need to try to build confidence so you can cut down on vacillation.
- **Phantom – Hidden Trouble:** These types of team members are nowhere to be found. They hardly make your meetings or want to be involved in your project. Unfortunately, these are the people that you need to make important decisions or your project cannot move on. They seem to be always busy for you and will rarely attend. You will learn how to maximize the time they will give you.

These types of characteristics may seem hard to control, but how can you control them? Simple you will need to be sure that they are included early in the game. It is best to communicate often. I like to follow the Lewin's change model which is an easy and self-explanatory for managing change as well as people. Lewin teaches us the three different stages of change, which is a useful methodology for any project since most of them are constantly evolving. The first step is to create the inspiration to change which Lewin calls it as the unfreeze step. The next step progresses through the change process by advancing to an efficient communications and allow people to embrace new ways of functioning with change. When you accomplish a stage of stability this is called refreeze, this is essential in order to create the assurance from which to get on the next unavoidable change (Lewin, 1951).

Our team members' personalities are a display of their characteristics. Personalities have a lot variation, no one single personality is perfect. We need to accept the fact that personalities are complex. Sometimes a person with bad behavior may not know they have this behavior. Therefore, the person doesn't adapt well to changes. You will need to have a strategic plan that includes com-

munication, methods to stop rumors and control your team's toxic behavior. How to accomplish this? Sure you can try to use one the most commonly used theories, methodologies and other tools, which are wonderful. However, the simplest way to accomplish this is to just keeping it simple.

I have found in my experience as a project manager that following steps are often better than complicating things; the following are the PM TEAM steps that I found to be helpful:

- **Put it in Writing:** You will need to formalize your expectations in writing in order to serve as a constant reminder; people tend to forget whether it is on purpose or not.
- **Make a Deal:** Be specific with your team on the type of dedication you required by them. You need to tell them the objective, the results and what you are trying to achieve at the specific time and additional details such as cost and resources, do not be vague.
- **Talk to Negotiate:** Sometimes there is a need for you and your team member's to negotiate timeframe. You will need to be flexible, but not too much. For the most part, you will need to be able to meet people's requests.
- **Explicit:** All your requests will need to be very clear, it will make easier for the person to provide you with their estimate and commitments. You need to keep in mind that just because you put it in writing and made it explicit doesn't make it and command, you will still need to monitor and control. Your team needs you to provide them with specific goals; they don't need to know how you are going to measure the tasks, but also the results.
- **Accountability:** You will need to be a role model and live up to what you promise. If you are a transparent project manager you will avoid misunderstanding or gossip. Accountability also implies to possess the liability and power to do something and totally acknowledge the risks of the results of those actions.

Figure 3. Simple steps to control negative resources

- **Minimize:** You can minimize the pressure that your team will experience through out the project by motivating them and have a check and balance system. This is to check your team temperature and see how things are going.

The best advice is for a project manager is to stay calm, be straight and show the way. Most project managers will rely on their basic management skills, which are leading, negotiating, problem solving, influence and communication. These are good skills; however you will need to develop an aptitude assessment to recognize the characteristics of people that can ruin your project. It is necessary to spot the bad behavior and change it to your own advantage. The project managers' job is not to squash the bad personalities, but it is to use them for the success of the project. You also need to know how to foster a healthy environment for the team members that are different and to help them to come collectively and carry out.

Generally, it will be necessary for a project manager to change communication methods with each individual, as you know what they say; "everyone is different and have different needs". An example is if you have a touchy team member you will need to be direct and factual when talking to them. You need to also assess their skills not and not just the bad behavior so you can match them with the appropriate tasks.

FUTURE RESEARCH DIRECTIONS

Understanding Team Formation

Even thou you will have your project team for a short-term, it can take time to gel them into one. This typically follows familiar phases; the project team travels to become a unified team with a same goal. Bruce Tuckman, Psychologist, was the one that developed the concept of "forming, storming, norming, and performing" back in 1965. There is a path that a team must follow to reach formation

and become a true team. These are great concepts and will work for the most part, but it is important to study human personalities and characteristics as much it is as important to manage and adopt tactics to manage them.

Recommendation for futures research direction is to start examines the up-and-coming movement regarding team project manager dealing from different point of views such as networking, strategic interpersonal commitment methods. Team project managers find themselves on the take-off point providing last arrangements to jump ahead of organization "best practices". You should learn more about how project managers recognize, choose, act, and achieve their goals. (Lord & Brown 2004). While a great deal regarding team development has been written, people still need to learn a lot. Organizations try to employee teams and promote teamwork, yet there is very limited understanding on how to really develop a teams and control resources. The only way to know is through research, lesson learned and one own experience.

A team typically follows a different pathways or stages when seeking to become a productive team, this is described by psychiatrist M. Scott Peck in his book *The Different Drum: Community Making and Peace*. He mentions how a team must go through chaos and denial as part of the transformation. Therefore, project managers or leaders should not be in denial themselves by avoiding these chaos and ignoring the fact that some personalities will be the natural disaster of your project. The chaos that Peck is referring to is the differences of opinion and viewpoint that exist between the members in the group. Project manager or leader will be the target of outbreaks and this is when they need to understand overall dynamic, it is no time to give up in despair, swearing that the team of people will not be able to work together successfully.

The quality of your project team is frequently an important success factor. You will need to be sure you don't let them feel like they are your hostages. Because project team members who want

Figure 4. Team formation quick overview

to leave and are held against their will, they will make sure your project is a failure. It's healthier to allow them to leave, this will avoid for them to bring down the rest of your project team into their bad behavior pit. I would rather have quality than mediocrity as a team.

CONCLUSION

It is important to select the right team members. Some project managers will be lucky to have this coming to them naturally; others will need to work at it. It is about trying to familiarize yourself with your team members, their forte, and connecting their knowledge and experience with the project at hand. This is a difficult task and will require for you to have a smile on your face, even when you do not feel like it. You will need to connect and talk with your team on a regular basis. Besides getting to know your team's bad behavior, it is important to develop great relationships. You will be surprised how your team will want to join forces with to complete the project on time and within

budget if you curate and foster a perfect balance. Projects will need to be guided in a manner that creates agreeable outcomes while at the same time mitigating the risks and/or erecting barriers. We as project managers will need to paint a picture of encouragement and inspiration for our team's abilities for them to identify with that vision.

In conclusion, team can be complex because of the diversity of team members even if you are well organized. It is more complex in organizations that have a matrix environment. Project team members in a matrix environment have various allegiances and if the team is not well organized, they can be dangerous to the success of the project. You can make your team more interconnected and triumphant by identify the types of characteristics your team has as well as assessing their needs as individuals, so that your methods can be properly executed with the desired results. The key is to identify potential drawbacks that may impede good team dynamics to flourish, address team members conflicting personalities or characteristics early in the game. You can definitely develop a more productive and successful team by doing so.

KEY TERMS AND DEFINITIONS

Characteristics: A personal quality, attribute, or trait.

Diversity: Considerable exceptionality of each individual, our difference from each other's.

Forming: Introduction phase of team members, everyone is getting to know each other.

Management: The process of controlling things or people.

Methodology: Set of practices perfection by someone else to guide you to do certain things.

Norming: Productivity phase, now team is concentrating on working toward project goals.

Performing: Team matures and is settling their expectations.

Storming: Phase where team is learning how to handle conflict.

Theory: It is a set of guidelines developed to explain an observable fact.

Triple Constraint: These are important elements (budget, scope and time) that need to be controlled efficiently for a triumphant completion of a project.

Making Sense of IS Project Stories

Darren Dalcher

University of Hertfordshire, UK

INTRODUCTION

Stories of failure make a compelling read, however, researchers with a keen interest in information systems failures are faced with a double challenge: Not only is it difficult to obtain intimate details about the circumstances surrounding such failures, but there is also a dearth of information about the type of methods and approaches that can be utilised to collect, describe and disseminate such information. The purpose of this chapter is to highlight some of the available approaches and to clarify and enhance the methodological underpinning that is available to researchers interested in investigating and documenting phenomena in context-rich and dynamic environments. The chapter begins by framing IS project failures in context, before highlighting the role of forensic failure investigation and the typical tools employed in gathering information. It encourages a move from case studies to case histories to capture the essence, dynamics and complexities of failure stories. It concludes by introducing a new range of antenarrative approaches that represent future developments in the study of IS failures, enabling a richer interpretation of linked factors that underpin IS failures.

BACKGROUND

The popular computing literature is awash with stories of IS project failures and their adverse impacts on individuals, organisations, and societal infrastructure. Indeed, contemporary software development practice is still characterised by runaway projects, late delivery, exceeded budgets,

reduced functionality and questionable quality that often translate into cancellations, reduced scope and significant re-work cycles (Dalcher, 1994). The net result is an accumulation of waste typically measured in financial terms. For example, in 1995 failed US projects cost \$81 billion, with an additional \$59 billion of overspend, totalling \$140 billion (Standish 2000). Jones contended that the average US cancelled project was a year late, having consumed 200% of its expected budget at the point of cancellation (Jones 1994). MacManus and Wood-Harper (2007) reported that the cost of software project failure across the European Union in 2004 was €142 billion. More recently, a McKinsey-Oxford survey of more than 5,400 software projects revealed that half of all projects significantly fail on budgetary assessment, while 17 per cent of projects actually threaten the very existence of the company, with the average project running 45 per cent over budget and seven per cent behind schedule, while delivering 56 per cent less functionality than predicted (Bloch et al., 2013).

IS failure investigations start with extensive attempts to collate relevant evidence. However, in most cases the researcher is exposed to specific information post-hoc, i.e. once the failure is well established and well publicised and the participants have had a chance to rationalise their version of the story. Most of the available sources are therefore already in place and will have been set up by agencies other than the researcher.

The purpose of a forensic investigation is to explain a given failure by using available information and evidence. The term Forensic is derived from the Latin 'Forensis', which is to do with making public. Forensic Science is the applied use of a body of knowledge or practice in deter-

mining the cause of death. Nowadays extended to include any skilled investigation into how a crime was perpetrated. Forensic systems engineering is the post-mortem analysis and study of project, product, artefact or service shortfalls and failures, which aims to uncover systemic and underpinning causes (Dalcher, 1994). The work involves a detailed investigation of a product or service, the underpinning project, its environment, decisions taken, politics, human errors and the relationship between subsystems. The work draws upon a multidisciplinary body of knowledge and assesses the project from several directions and viewpoints. The aim of forensic analysis is to improve the understanding of failures, their background and the dynamics that lead to them. The concept of systems is a central tool for understanding the delicate relationships and their implications in the overall project environment.

Forensic systems engineering is primarily concerned with documentary analysis and (post-event) interviews in an effort to ascertain responsibility lines, causal links and background information. The primary mode of dissemination of findings, conclusions and lessons is through the publication of case study reports focusing on specific failures. However, there are limited research methods to explore the dynamic and fragmented nature of complex failure situations. Lyytinen and Hirschheim (1987) noted that more qualitative research methods were needed for IS failure research as well as more extensive case studies that explored problems in more detail and viewed solution arrangements in light of what transpired. The same methods also need to account for group issues and cultural implications. Sadly, thirty years on, the same constraints in terms of methods are still in evidence.

DESCRIBING FAILURE

Making sense of IS failures retrospectively is difficult. In general, there is very little objective quantitative failure information that can be relied

upon. Instead, interpretation requires understanding of and engagement with the wider context. Indeed, a specific feature of failure is the unique interaction between the system, the participants, their perspectives, complexity and technology (Perrow, 1984). Lyytinen and Hirschheim (1987) pointed out that failure is a multifaceted phenomenon of immense complexity with multiple causes and perspectives. Research into failures often ignores the complex and important role of social arrangement embedded in the actual context. This is often due to the quantitative nature of such research.

Understanding the interactions that lead to failures likewise requires a humanistic stance that is outside the conventional positivist norm to capture the real diversity, contention and complexity embedded in real life. Forensic analysis thus relies on utilising qualitative approaches to obtain a richer understanding of failure phenomena in terms of action and interaction.

The fact that a failure phenomenon is being investigated, suggests that attention has already been drawn to the complexities, breakdowns and messy interactions that such a situation entails (i.e. the investigation is problem-driven). Many such inquiries deal with subjective accounts including impressions, perceptions and memories. The aim of the researcher is to increase in a systemic way the understanding of a situation, yet do so from a position that takes in the complexity of the entire situation and incorporates the different perspectives and perceptions of the stakeholders involved.

Overall, the purpose of a failure research method is to enable the researcher to make sense of the complexity of detail and the complexity of interaction and chart the contributory role of different causes and issues in the build up to failure. However, the armoury of research methods in this domain is often limited to case studies.

The term “case study” is an umbrella term used in different contexts to mean different things that include a wide range of evidence capture and analysis procedures. Yin (2013, p.14) defines the scope of a case study as follows:

A case study is an empirical inquiry that:

- *Investigates a contemporary phenomenon in depth and within its real-life context, especially when*
- *The boundaries between phenomenon and context may not be clearly evident.*

A case study can be viewed as a way of establishing valid and reliable evidence for the research process as well as presenting findings which result from research (Remenyi, 1998). According to Schramm (1971) the case study tries to illuminate a decision or a set of decisions and in particular emphasise why they were taken, how they were implemented and with what results. A case study is likely to contain a detailed and in-depth analysis of a phenomenon of interest in context; in our case, the failure scenario. Table 1 summarises some of the main advantages of using case studies.

The general aim of the case study approach is to understand phenomena in terms of issues in the original problem context by providing the mechanism for conducting an in-depth exploration. They often result from the decision to focus an enquiry around an instance or an incident, as

they are principally concerned with the interaction of factors and events. The combination of a variety of sources offers a richer perspective which also benefits from the availability of a variety and multiplicity of methods that can be used to obtain new insights about this single instance. A Case study allows the researcher to concentrate on specific instances in their natural setting and thereby attempt to identify the interacting perceptions, issues and processes at work, ultimately resulting in in-depth understanding. Crucially, the focus on a single incident thus enables the study of the particularity and complexity of a case, thereby coming to understand the activity within important circumstances (Stake, 1999) whilst including multiple sources of evidence and differing perspectives.

There are a number of general objections that are associated with the use of case studies (see Table 2). However, one must recognise that case studies are more likely to be used retrospectively rather than as an on-going perspective (especially from a failure point-of-view), as researchers are unlikely to know the potential for useful results and interest from the outset and may have difficulty in negotiating access to the location. Indeed, Yin (2013) concedes that using case studies for research purposes remains a most challenging endeavour.

Table 1. Main advantages of using case studies

• Ability to identify and focus on issues • Richness of detail • Multiple perspectives • Multiple sources and types of data • Multiple explanations (no absolute truth) • Cross disciplinary remit • Ability to recognise and minimise inherent complexity • Ability to handle conflict, disparity and disagreement • Ability to show interactions • Ability to observe emerging patterns • Opportunity to focus on the particular • Ability to gain real insight and understanding of a situation • Conducted in real-life (natural) setting • Encompasses original problem context • Ability to deal with interpretations • Features intensive analysis • Can extend the boundaries to include aspects of wider system environment • Can be accumulated to form an archive of cases • Can be strengthened and expanded with longitudinal features • Often retold in story format, which is more accessible to practitioners
--

Table 2. Main objections to the use of case studies

• Sometimes viewed as soft data (but some argue it is hard research) • Biases inherent in accepting views and perceptions • Questions about generalisability of findings (especially from a single case), but it is possible to build a library of such cases • Issues regarding objectivity of approach and perceived lack of rigour • Negotiating access to settings • Boundaries are difficult to define; but this could also be a strength! • Mainly retrospective • Sometimes viewed as likely to take too long and result in massive documentation • The observer effect • Reliability of conclusions • There is little control over events, but this may also be a strength
--

Comprehensiveness of coverage is not necessarily a requirement. The richness of detail can be controlled through the careful placement of systems boundaries and consideration of the wider system environment that is relevant to the specific phenomenon under study. Case studies can be utilised as a source of understanding, which is tolerant of ambiguity, paradox and contradiction. A case study is viewed as interpretative when events in the real world are observed and then an effort takes place to make sense of what was observed, i.e. when one tries to make sense of a failure from the perspectives of participants. They also offer the potential for generating alternative explanations from the different stakeholder perspectives, thereby allowing the researcher to highlight contradictions, conflicts and misunderstandings.

FROM CASE STUDIES TO CASE HISTORIES

The generally liberal use of the term *case study* requires a tighter definition of its meaning in failure research. While there may be a tradition of using case studies within the IS community, this is perhaps more often borrowed from the MBA culture than as a result of self conscious effort to adopt them as a research approach (Walsham, 1995; Cornford, 1996). Indeed, the case study is typically used more in its capacity as a teaching tool than as a research tool. The shift to studying the impact of issues within the organisational context renders case studies particularly useful for investigating failure scenarios. However, the use of the term often leads to some confusion.

Moreover, one of the major complications in failure investigations is in relating causes to effects through extended time horizons (Dalcher, 2000). The implications of actions may not be witnessed for years, or even generations. Delays between making a decision and observing the result distort the causal link between the two. As a result, people tend to associate a different level of severity to events occurring following a delay. The perceived severity is thus diminished with

the length of the delay further complicating the task of identifying patterns and interactions that contributed to a given failure. Failure researchers are thus required to provide adequate historical accounts of the interaction between actions, perceptions and the passage of time.

Case studies have typically been used to explore issues in the present and the past and comprise of ethnographic studies, single case studies and comparative case studies, as well as, action research, evaluative, exploratory, explanatory and descriptive case studies. In our experience there is a need to add the failure case study as a special example of a case study focusing primarily on the background, context, perception, interactions and patterns, especially as the failure investigation is likely to take place after the (failure) event. We thus propose the use of the label case histories to refer to the retrospective and specialised historical research studies focusing on failure incidents.

The time dimension (sequencing) is critical to understanding interactions and identifying their impacts when stories are constructed. Case histories are concerned with providing the background and context that are required to endow words and events with additional meaning. Background refers to previous history of the system itself, while context refers to interactions with the environment. As failures are time- and place-dependent, the case history framework enables readers to obtain an understanding of the intimate context surrounding the main event. The primary tool available to the community is the Case Histories of failures (derived from the use of the case study method). These represent a detailed historical description and analysis of actual processes from a relevant perspective. Their value is in tracing decisions (and recorded rationale) to their eventual outcomes by utilising techniques borrowed from decision analysis and systems engineering. Indeed, the historical description and presentation of a chronology of events infused with meaning, intention and understanding are based on the recognition that real life is ambiguous, conflicting and complex.

Case histories thus contain observations, feelings and descriptions. They can be used to

construct, share, dispute and confirm meanings, interpretations and scenarios in the context of real events (See for example, Dalcher, 2004; 2007). Rather than simply highlight a chronicled sequence of happenings, they convey a story encompassing a specific perspective, focus, and possibly some inevitable biases. The interpretation plays a key part in transmutating the chronicle into a meaningful story with plot, coherence and purpose. However, constructing a convincing narrative of a complex story with competing meanings, alternative perspectives and inherent prejudices is a challenge in itself.

FUTURE TRENDS: EMERGING NARRATIVES

Failures, in common with other activities that take place in organisations, are based on stories. The verbal medium is crucial to understanding behaviour within organisations and systems, and researchers are thus required to collect stories, grounded in practice, about what takes place (Gabriel, 2000; Simmons 2007). Gargiulo (2005) further asserts that effective organisational communication and learning is dependent upon stories: Listening to them is critical to the success of the organisation. Understanding failures often entails the retrospective untangling of complicated webs of actions and events and emergent interaction patterns. Failure storytelling can thus be understood as a combination of narrative recounting of empirical events with the purposeful unlocking of meaningful patterns, or a plot.

Historically, story telling has been an acceptable form of conveying and sharing ideas, norms, values, experience and knowledge of context. It plays a key role in communicating the cultural, moral or historical context to the listener. Indeed, Arendt, (1958) argued that the chief characteristic of human life is that it is always full of events, which ultimately can be told as a story. There are even strong claims that the narrative is the main mode of human knowledge (Bruner, 1990), as well

as the main mode of communication, learning and thinking (Fisher, 1987; Gargiulo, 2005; Denning, 2011). Moreover, children are often initiated into culture (and its boundaries) through the medium of story telling, offering models for emulation or avoidance.

In practice, the essence of any good case study revolves around the ability to generate an effective storyline, normally with a unique style, plot or perspective. In a large case, a general theme can be obtained from selected excerpts weaved together to illustrate a particular story. This is particularly useful when the researcher is trying to portray a personal account of a participant, a stakeholder or an observer in an incident, accident or failure. The implication is that the need to address personal aspects of interaction and story is fulfilled by the development of a research-valid narrative. Indeed, Remenyi et al. (1998) contend that a story, or a narrative description, is valid if the resulting narrative adds some knowledge. Furthermore, White (1973) describes a story as 'the process of selection and arrangement of data from the unprocessed historical record in the interest of rendering the record more comprehensible to an audience of a particular kind' by inserting a sense of perspective and purpose.

Storytelling can endow listeners with different meanings as stories can be understood in multiple ways. Narratives are neither discovered, nor found: they are constructed. Understanding IS failures is therefore more complicated than the discovery of a simplistic chronology of events as stories are crystallised through infusion with meaning and context. Narrative inquiry is evolving into an acceptable research approach in its own right in the social sciences and in management research circles (Gabriel, 2000; Boje, 2001; Czarniawska, 2004; Boje, 2011; Boje, 2014) as the story format provides a powerful way of knowing and linking disparate accounts and perspectives. When different accounts are combined, the emerging story line benefits from the richness of multifaceted insights.

Developing a narrative requires plot as well as coherence as a story is made out of events and

the plot mediates between the events and the story (Boje, 2001; Carr, 2001; Kearney, 2002). The narrative can thus become a powerful mechanism for eliciting and sharing experience in a meaningful way through intimate reflection. In failure stories, the plot often emanates from the actions and perceptions of participants emerging out of the flux of events, in (direct) contradiction with expectations. The storyteller is concerned with the perspective and purpose of participants as well as with the plausibility of the emerging plot. The combination of plot, purpose and perspective dictates the selection of elements, the filling in of links and the removal of 'irrelevant' noise.

Post-modern interpretation contends that most real life stories are fragmented, non-linear, discontinuous, multivariate and incoherent. This has already been highlighted as a feature of failure stories. Such stories also tend to be dynamic, polyphonic (multi-voiced) and collectively produced as they occur in asymmetrical, random and turbulent environments full of tensions and ambiguities. The stories are not plotted as such and they appear to flow, emerge and network offering complex clustering of events, emergent phenomena, causes, interventions, interferences and effects. Moreover, the accounts are often subjective, counter-intuitive and contradictory. This leads to interacting, and conflicting webs of narratives, characterised by coincidences, predicaments and crises.

Generally, stories appear to be improperly told, as a story is an 'ante' state of affairs existing previously to a carefully constructed narrative (Boje, 2001). The antenarrative, or the 'real' story, is the fragmented, messy and dynamic, multi-vocal, multi-plotted, multi-version and complex tale. Indeed, modern story-tellers look for new ways and mediums for weaving and depicting a multi-vocal reality, as exemplified by Mike Finggis's digitally shot film *Time's Arrow*, where the screen is split in four to allow for four separate perspectives and sub-stories that occasionally intersect or overlap. In the tradition of post-modern inquiry, a real life researcher is often faced with fragments rather than a whole story to tell; and many of the fragments

may reflect contrary versions of reality. This is potentially more acute when the accounts attempt to justify roles of participants in the lead-up to disaster or failure. It would also appear from past analysis that there are hierarchies of stories and stories that exist within, or interact with other stories. Using the terminology provided by Boje, the purpose of narrative methods is to take a complex situation characterised by collective (yet often conflicting) memory and an antenarrative and construct the plot and coherence that can be used to narrate and guide the story of interest.

The reality in failure stories is of multi-stranded stories of experiences and reactions that lack collective consensus. Indeed the discipline of decision-making has also recognised that making choices is about forming and selecting interpretations from a mosaic of possibilities (March, 1994; Weick, 1995). Not surprisingly, disasters, or traumatic stories, are hard to narrate, understand and justify. Stories have three basic properties: time, place and mind (Boje, 2001) which interact and build up as the story evolves. In forensic case histories, these are further clarified through the identification of the background and context, which clarify and justify the interpretation in the context of the emerging phenomena.
